The condensing plant is arranged as indicated in Fig. 5. A Richardsons-Westgarth "Contraflo" condenser is used, but the circulating pump is placed at the low-pressure side, so that the water is drawn through, and undue pressure at the end of the condenser is avoided. It had been found necessary to strengthen the end of the condenser of the former machine on this account, and the same alteration in the arrangement has now been made in it. The circulating pump is of the De Laval centrifugal type, with a capacity of 9,175 gals. per min. by 99 ft. total head. It runs at 725 revs. per min., and is driven by a Siemens 375 b.h.p. three-phase motor, run off the 400-volt A.-C. station bus-bars. The use of three-phase motors for the auxiliaries is a departure from the practice hitherto followed at Stuart Street of using D.-C. motors for them. A squirrel-cage motor is employed, with an auto-transformer for starting.

The air-pump is a Richardson-Edwards three-throw motor-driven pump calling for no very special description; it is driven by a 55 b.h.p. slip-ring motor. A De Laval motor-driven vertical pump (Fig. 7), made by Messrs. Greenwood & Batley, Ltd., pumps the water from the condenser to the hot-well. As an alternative, a force-pump fitted to the end of the air-pump shaft can deal with the condensed water, but normally it simply deals with injected spray water. It is capable of lifting 250 gals. per min. 94 ft., and is driven at 1,450 revs. per min. by a 16-b.h.p. three-phase motor seen in the illustration.

The circulating water is at present cooled by the existing cooling-tower plant, the latest additions to which, two fine natural-draught cooling-towers made by the Blasberg Engineering Co., Ltd., were described in detail in our issue of June 10th. These are also illustrated in a photograph on another page of the present issue. A second pair of cooling-towers similar to these but somewhat higher has been ordered from the Blasberg Engineering Co., and will shortly be in commission.

In concluding this article we may refer briefly to the special care taken in the design and construction of the foundations and to prevent any inrush of water to the turbine, two points which are frequently overlooked. We understand that the whole set is giving great satisfaction to the authorities, and to Mr. Pearce in particular the result must be extremely gratifying in the light of the opinions he has expressed on several occasions in favour of the Zoelly type of turbine.

THE BLYTH'S WHARF ELECTRICITY WORKS OF THE STEPNEY BOROUGH COUNCIL

THE carrying out of the scheme for the construction of a large new riverside electricity works at Blyth's Wharf, Limehouse, to meet the growing needs of the Stepney district may be said to have had its inception in 1903, as it was in this year that the site was purchased by the Stepney Borough Council. Owing partly to uncertainty regarding the fate of the various London Power Bills successively brought before Parliament, however, no commencement was made upon the buildings until last year, but the growth of the load was very rapid in the meantime, and additional plant is absolutely necessary to deal with the coming winter load. The work has therefore been pushed forward so that the first instalment of plant at the new station inaugurated yesterday will be ready immediately to take a share in the load. As will be seen below, however, the equipment is still far from complete.

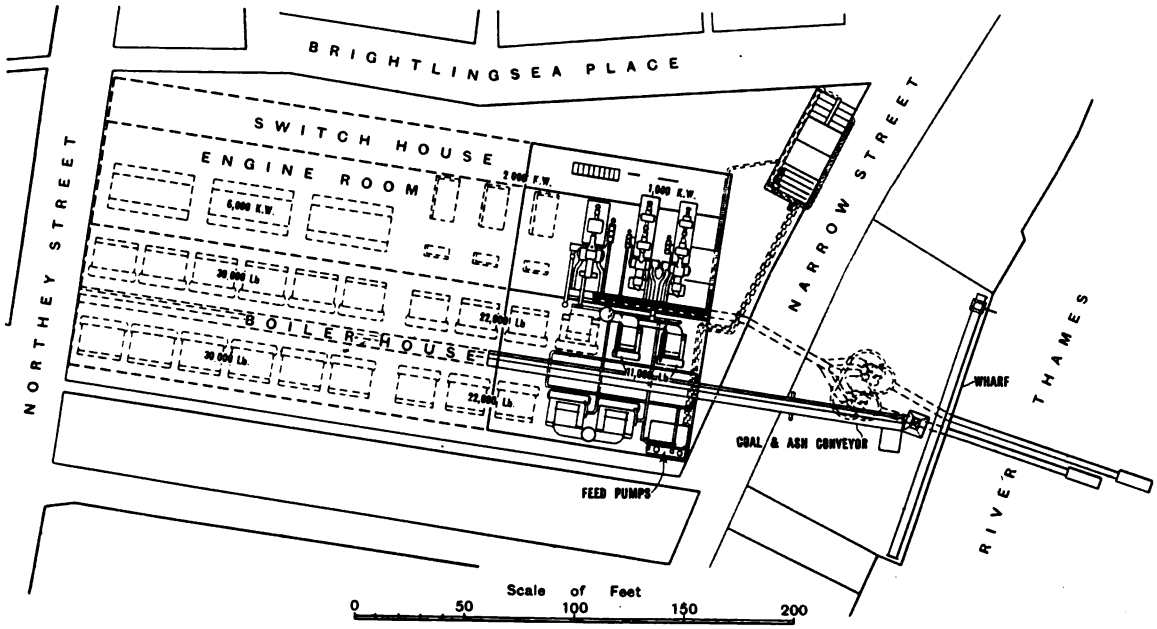

FIG. 1.—PLAN OF STATION SHOWING COMPLETE PROJECTED SCHEME.

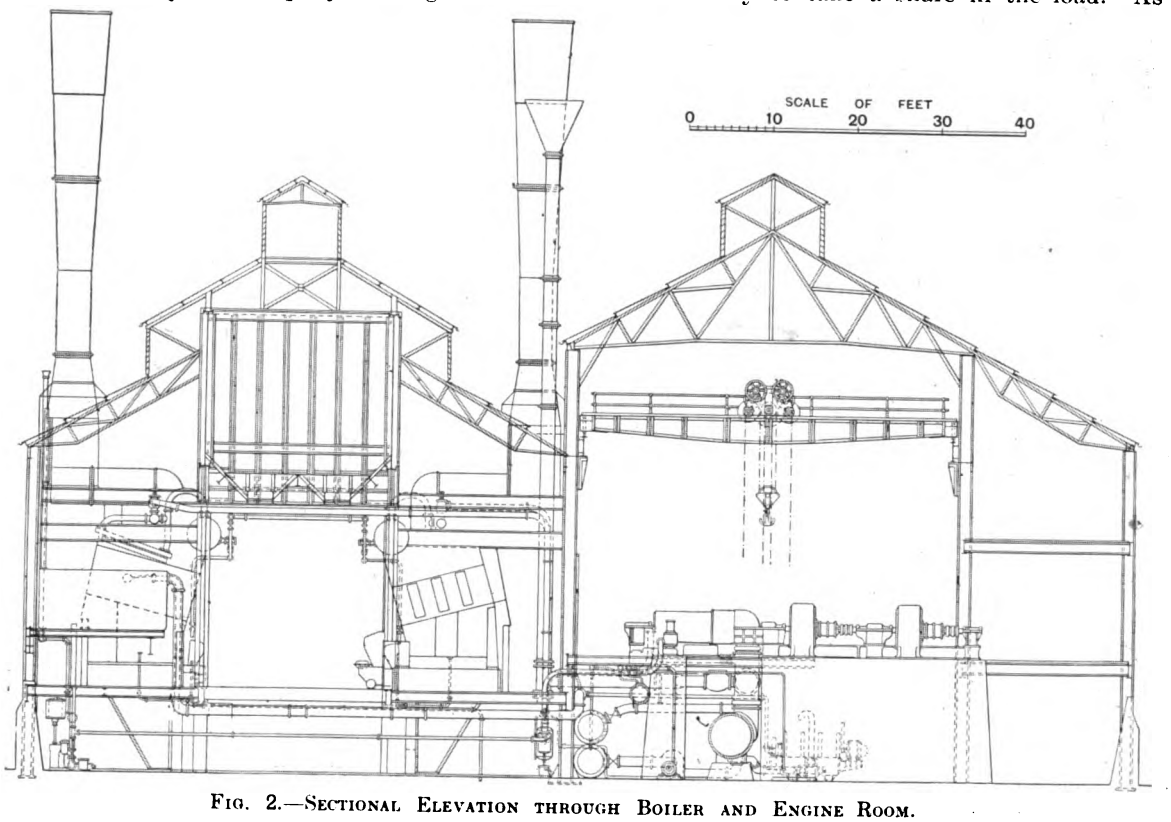

FIG. 2.—SECTIONAL ELEVATION THROUGH BOILER AND ENGINE ROOM.

Up to the present, supply has been carried out from the Council's original station in Osborn Street, White-

Digitized by Google

chapel, which contains plant aggregating some 2,720 kw., including, in addition to the old reciprocating plant, one 1,000-kw. Parsons turbo-generator, which will eventually be moved to Blyth's Wharf. As will be seen below, another set similar to this has already been transferred, and the space it occupied is now taken up by two new 1,000-kw. Peebles–la Cour motor converters for dealing with the H.T. supply from the new station. Certain boilers have also already been moved. At Osborn Street the turbines suffered

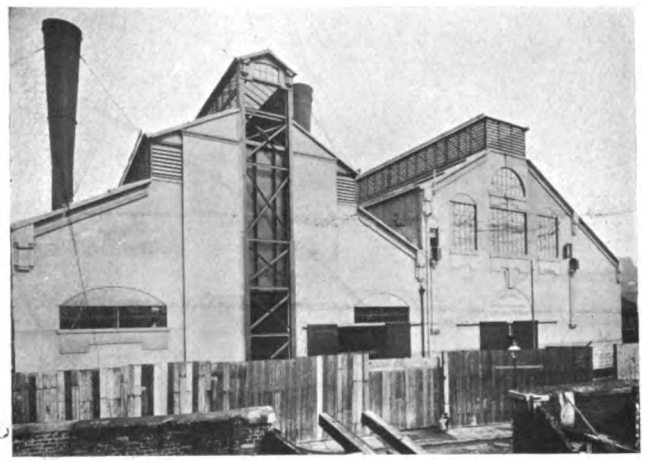

Fig. 3.—View of South End of Station.

from lack of facilities for condensing, but notwithstanding this, Mr. W. C. P. Tapper, Borough Electrical Engineer, has been able to obtain very creditable figures for works costs.

Turning now to the new station, the building itself, the cost of which was, we understand, not greater than £2·85 per kw., is interesting as being the first complete ferro-concrete building of its kind to be constructed under the new regulations of the London County Council. It is particularly well lighted, as the whole of the roof excepting the central portion of the boiler-house is one expanse of glass, reinforced with wire netting. The north end is temporary, and is closed by corrugated iron, and it is noticeable that this and all other corrugated iron, &c., used in the building is covered inside with a preparation of cork dust to prevent sweating. The proportion which the part now completed forms of the whole projected scheme can be seen in Fig. 1. The ultimate equipment is for 28,000 kw., of which the present building will accommodate 6,000 kw. Only a half of this is, however, now in place. The station simply consists of parallel boiler and engine houses, the latter provided with a commodious switch gallery. The section through the boiler and engine houses in Fig. 2 gives an idea of the general arrangement. A view of the south end of the building is shown in Fig. 3.

Coal will be obtained direct from the river by a simple arrangement of cranes, and an overhead conveyor leading direct to the bunkers over the centre of the boiler-room, and returning under the floor so as to be utilisable also for ashes. The coal-conveying equipment, however, is not yet complete, so that for the present the coal will be carted. The boilers will form two independent rows on each side of the boiler-room. At present there are on the east side a pair of Babcock & Wilcox marine type boilers, each of an evaporative capacity of 11,000 lb. per hour. These boilers have been moved from Osborn Street, but have had chain grate automatic stokers fitted to them. There is also space on this side for two further boilers of 22,000-lb. evaporative capacity. On the west side there is accommodation for three 22,000-lb. boilers, and of these one, a new B. & W. marine type boiler, with underfeed stoker, is already in place. A similar boiler, which will also be equipped with this form of stoker, has yet to be brought from the old station. It is interesting to note that the two sides of the boiler-house are absolutely independent, each with its own short steel chimney, and that the east side, which is provided with chain-grate stokers, is equipped with induced draught on the Pratt system, while on the west side forced draught is employed in conjunction with underfeed stokers. An excellent comparison of the two systems will thus be possible. The draught in each case is produced by a motor-driven "Sirocco" fan in the basement. The hot-well tank and feed pumps are situated in the south-west corner of the basement. One Wier compound steam pump is already installed, but this can be worked, if required, in two separate halves. The steam-piping installation was carried out by Messrs. Foster Brothers, of Wednesbury. The principal features of its arrangement are that practically all pipes are placed below the floor level, and are so hung as to be absolutely free as regards expansion. The position of the main header, which is the lowest part of the system, permits of very simple drainage arrangements at three points only. A 40,000-gallon feed storage tank, which was moved from Osborn Street, has been placed outside the main building on a ferro-concrete structure, which also contains the men's mess-rooms, &c., and an Archbutt-Deeley water-softening plant.

Two generating sets have been erected in the engine-room. One of these is the 1,000-kw. Parsons set from Osborn Street already referred to. This set, which can be seen in the background in Fig. 4, consists of a pair of four-pole continuous-current machines with compensating windings, to which slip-rings have also been fitted, making them into double-current machines with a continuous output each of 4,350 amperes at 230 volts, or an alternating output of 4,130 amperes at 140 volts, three phase, 50 cycles, at 1,500 r.p.m.

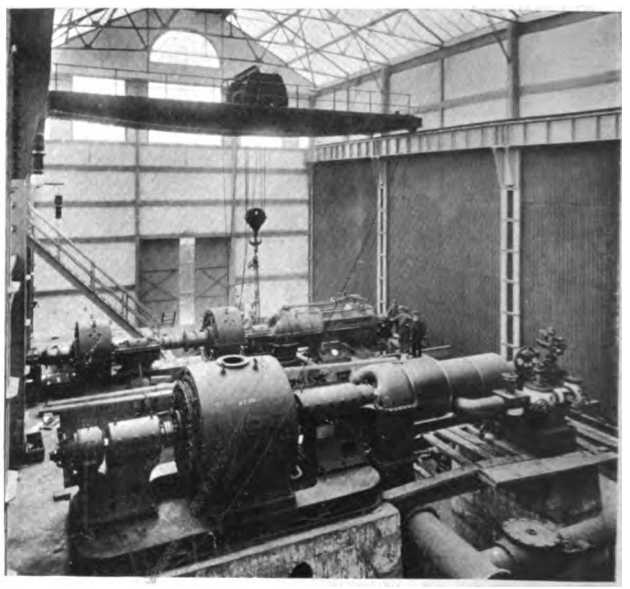

Fig. 4.—Interior of Engine Room.

The set can thus either feed direct into the 480-volt three-wire system, or can be used in conjunction with transformers to give a high-tension supply. The transformers in question will consist of a group of six single-phase air-cooled transformers of the Berry type, made by the British Electric Transformer Co., of Hayes, Middlesex. They are to be coupled in two sets of three in mesh, one set for each machine, and will transform up to 6,600 volts three phase. A similar group of transformers will also be provided for the second double-current set, which is to come from

Digitized by Google

Osborn Street. All these transformers will be placed in the basement under the switch gallery.

The other generating set is a new Willans-Bruce Peebles 2,000-kw. turbo-alternator. The turbine is of the standard Willans-Parsons design, of which many examples are to be found in the generating stations of this country, and runs at 1,500 r.p.m. The alternator has a rated output of 2,350 k.v.a. at 6,000 volts, three

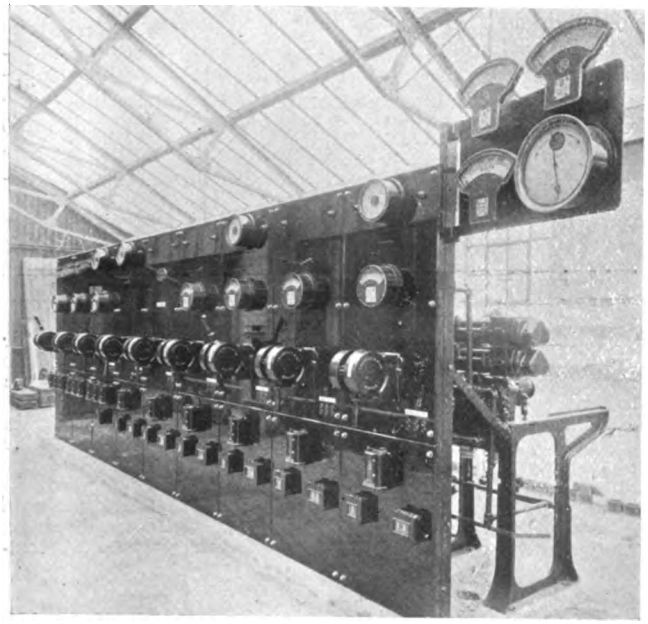

Fig. 5.—Operating Panels of H.T. Switchboard.

phase, 50 cycles, and follows Messrs. Bruce Peebles' latest practice. The rotor has four salient poles, the space between which is filled in with substantial wedges holding the windings in place. On each end of the rotor shaft are mounted fans which force air drawn in through a duct from the basement through the machine, and out by another aperture under the machine. The stator is, therefore, fully enclosed. An exciter is coupled to the shaft. The appearance of both these sets is much enhanced by the fact that the whole of the oil and bearing-cooling water piping, as well as the steam piping, is hidden below the floor level.

The condensing plant for each set is situated, as usual, directly underneath. Both condensing equipments are new, as the older set ran non-condensing when at Osborn Street. They are of the "contraflo" pattern, with electrically-driven Edwards air-pumps and Rees-roturbo circulating pumps, and were supplied by Messrs. Willans & Robinson. Practically the only difference in the two, except in their size, lies in the fact that the Parsons turbine is connected to its condenser through a "concertina" joint to take up expansion, while in the Willans set the condenser is bolted rigidly to the exhaust flange of the turbines, but is mounted on springs. River water brought in through 3-ft. pipes will be used for condensing. This pipework is not, however, yet complete, so the start is being made non-condensing. The river pipes will extend 150 ft. into the river, and will be arranged on the Bowden patent system, so that the direction of flow can be reversed from time to time.

The switchgear is arranged on three floors. In the basement, the only switches will be those on the low-tension side of the step-up transformers for the double-current machines. There is no feeder gear in this part of the building, but the entering cables simply turn upward and are taken up through the floor in earthenware ducts. The situation of the negative feeder board for the outgoing continuous-current 480-volt feeders is on the engine-room floor level; the positive board is above it in the gallery, and alongside this, also in the gallery, is the mid-wire or neutral board. These boards are being supplied by Messrs. Crompton & Co. Provision is made for four sets of bus-bars, which can be either kept at different voltages or coupled together.

The most interesting part of the switchgear is the high-tension board in the gallery, which is a fine example of the ironclad system developed by Messrs. Reyrolle & Co., of Hebburn-on-Tyne. The principal features of this system, which is in very extensive use on some of the power companies' systems in the North of England and elsewhere, were described in Electrical Engineering, Vol. IV. (July 2nd, 1908), page 24. The principal difference from the switchgear there illustrated, which was really of the substation type, is that instead of the operating handles being attached to the switch carriages, the position of the apparatus is reversed, and rods are carried through to slate panels, on which the hand levers, as well as the instruments, relays, &c., are fixed. Thus the vertical slate control board and the row of ironclad bus-bars and switch units are, so to speak, back to back. Fig. 5 is a front view of the operating panels, and the row of switch units at the back of the board is seen in Fig. 6. The actual oil switch in each case is mounted on a carriage running on steel rails on brackets at the side, so that it can be withdrawn for examination complete with its oil tank, &c., by drawing the carriage out. This action breaks connections to the feeder and the bus bars by the simple withdrawal of knife contacts entirely isolating the switch. Further, on withdrawing the switch carriage, a pair of cast-iron doors automatically come forward and close over the face of the chambers in which the live contacts are situated, and the reverse motion automatically folds them up and carries them into a special housing space. The doors can be locked so that access to the live conductors, under any conditions, is impossible. The contacts are purposely made stiff and of large surface, so that some force is necessary to withdraw them. A lever-and-ratchet arrangement is there-

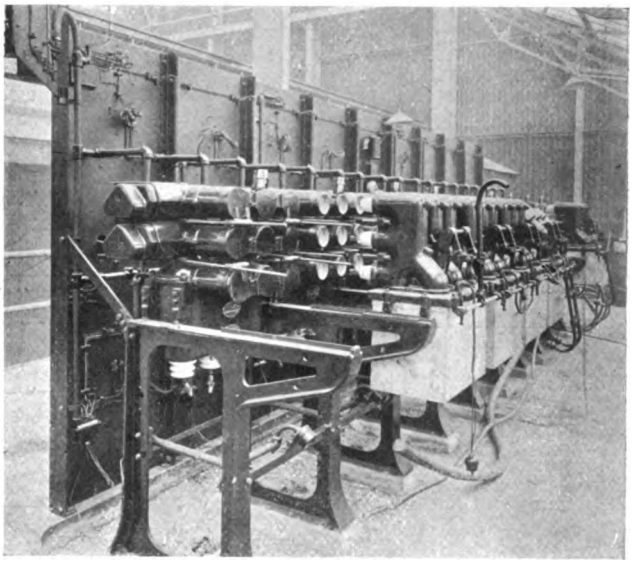

Fig. 6.—Back of H.T. Switchboard.
(The nearest switch carriage is removed, and the remainder are drawn forward.)

fore provided for racking the carriage into and out of position. The handle working this terminates in a plug forming part of the tripping circuit, so that it is impossible to draw the carriage forward until the switch is released. It is also impossible to close the switch unless the carriage is locked in place.

The board comprises on the right-hand side the necessary panels for the 2,000-kw. turbo-alternator, and for the supply through the step-up transformers from the double-current machines, and on the left-hand side the

Digitized by Google

feeder panels. Two pairs of 6,000-volt bus-bars are provided, and there is in the centre a bar-coupling panel by which they can be connected together or separated under load. Two of these feeders lead direct to Osborn Street, where they will be used in connection with the two 1,000-kw. motor converters already mentioned. The third is an interconnecting main to the electricity works of the Poplar Borough Council. Synchronising apparatus is provided on a hinged bracket at the end of the board.

It is interesting to note that the machine, as well as the feeder circuits, are protected entirely on the Merz-Price balance system (see ELECTRICAL ENGINEERING, Vol. III., page 763). For this purpose special pilot wires are run in connection with the feeders, and special current transformers are fixed in the basement, through which are threaded the machine cables close to the generator terminals.

Even if the station contains some items of plant moved from an older power-house, there are many points in its design which will render it, when a little more complete, one of the most up-to-date generating stations in the country. The responsibility for the general lay-out of the scheme and for the installation of the plant has fallen upon Mr. W. C. P. Tapper (Borough Electrical Engineer and Manager), while the buildings have been erected to specifications and plans prepared by Mr. M. W. Jameson (Borough Surveyor and Engineer). In concluding these notes, we wish to express our thanks to Mr. W. C. P. Tapper, who placed at our disposal the drawings and some of the photographs from which the accompanying illustrations are prepared, and afforded other facilities; and also to Mr. A. W. Heaviside, under whose superintendence the plant was erected, for conducting our representative over the works.

RECENT DEVELOPMENTS OF THE O.S. WIRING SYSTEM

MESSRS. SIEMENS BROS. & CO. (Caxton House, Westminster) have sent us a copy of their latest pamphlet dealing with their "O.S." wiring system, and we have also had an opportunity of inspecting some slight modifications and improvements they have made in this method of wiring. It will doubtless be remembered that, in its simplest form, the wiring is carried out by means of wire and cable insulated with vulcanised rubber and covered with a casing of tinned copper. As an alternative insulation, the firm are now supplying an unvulcanised compound, and in the case of wires intended for use with an earthed concentric system, they are adding, if

FIGS. 3-5.—SCREW CLAMPS FOR CONCENTRIC WIRING.

FIG. 6.—"FROG" CLAMP FOR FLUSH WORK.

FIG. 2.—SIDE-ENTRY EARTHING CLAMP FOR ORDINARY WIRING.

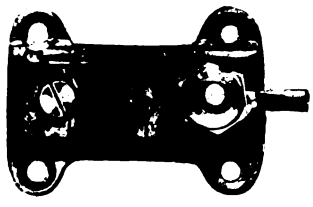

FIG. 7.—EARTHING 'BUS-BAR.

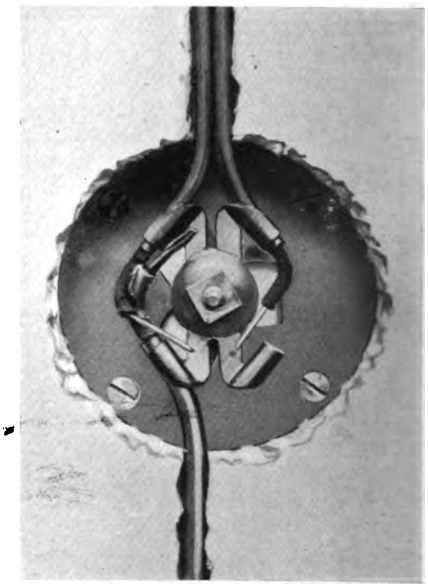

FIG. 8.—BACK PLATE WITH "FROG" CLAMP FOR FLUSH WORK FIXED IN POSITION.

in Fig. 2 are for a pair of cables, and the fourth way for three cables, as for a switch on a looping-in system. The clamp illustrated is for cables entering at the side, and a modification is employed for back-entry.

Figs. 3, 4, and 5 show the clamps used on the back plate in place of the earthing clamp for concentric wiring. These give an extremely firm contact.

Another new accessory is the "frog" clamp shown in Figs. 6 and 8 for flush work. Fig. 8 shows a back plate of the pattern illustrated in Fig. 1 used with a "frog" clamp (Fig. 6), and fixed under the surface of the plaster. A temporary cap made of cardboard is fixed over this to protect it during plastering.

Fig. 7 is a "continuity" 'bus-bar for earthing the sheathing at distribution boards. The illustration represents a 4-way bar, and it is seen that each of the set-screws clamps two cables. Similar bars are made for 8-way and 16-way boards.

Where the back plates and clamps described are used simply for joints, without fittings, steel covers take the place of wooden blocks. When these would be too large or unsightly, however, or in cases where an absolutely water-tight joint is essential, a neat junction-box is used. The wires are soldered into small channels of soft metal, which are provided with "nibs" to grip the wire before soldering. These are laid in porcelain interiors, which in their turn fit into the junction-

required, an aluminium taping between the insulation and the tinned copper sheathing to increase the conductance of the latter, and so to diminish the potential drop on the bare return conductor.

A useful modification has been made in the "continuity fixtures" for rendering the sheathing continuous behind the switches and fittings. Figs. 1 and 2 show the new back plate and earthing clamp respectively. The diameter of the plate is now $2\frac{3}{4}$ in. instead of $3\frac{1}{2}$ in., and this can therefore be used with a 3-in. wooden block, which is chamfered inside so that the back plate is covered by the block, and the block is flush against the wall. The earthing clamp is now made as in Fig. 2, and clamps the cables tighter than the former pattern, in which the outer rim of the clamp was not split. Three of the four ways

Digitized by Google

box. The box is of soft metal, and is so designed that solder can easily be run round the joint between the base and the cover, and "nibs" similar to those on the inside jointing-pieces are provided at the outlets to facilitate soldering the sheathing to the box.

Not the least useful part of the catalogue is the detailed instructions at the end for erecting the O.S. system of wiring, and these, we understand, will be reprinted in pocket-book form for the convenient use of the wireman.

On Saturday last the students attending Mr. E. Kilburn Scott's lectures on "Quantities and Estimates," at the Northampton Institute, visited the new factory and laboratory of Messrs. Fletcher, Fletcher & Co., Seven Sisters' Road, to see the electrical installation. Mr. W. R. Rawlings, of Rawlings Bros., Ltd., who has carried out the work, was present to describe the details and to give particulars of the quantities of material used, &c. The installation illustrates the O.S. (Stannos) system of wiring for (1) a two-wire system; (2) a surface concentric system; (3) a water-tight concentric system with Kalkos fittings; and (4) a combination of 2 and 3 in buried work. The supply for the lighting is taken from the Islington Corporation at 100 volts (or 200 if desired), alternating single-phase 50 cycles. Twin armoured cables pass from the Corporation fuses through an iron-clad L.P. switch and fuse to the first floor, terminating at a Foster double-wound transformer, giving 100 volts on the lamp side, and taking 100 or 200 volts as desired on the supply side. In conjunction with the transformer there is a Bruston automatic switch to disconnect the primary circuit when no lamps are in use. Distribution from this point is made from a four-way board, one pole of which is connected to a 'bus-bar forming the return of an earthed concentric system. From this point single cables drawn into Kalkos tubes are carried to four distributing boards, the tubes being connected to the earthed 'bus-bar. From the fuse-boards, the O.S. system of wiring has been employed, using Stannos wire and fittings, together with the special continuity fixtures provided for concentric work. On the top floor, and a portion of the ground floor, the system has been made water-tight by soldering the Stannos wires into Kalkos-boxes.

In addition to the before-mentioned "earthed" system, two pilot lights have been installed on the ground floor, two Stannos wires being used in the ordinary way without the intervention of the transformer.

The number of points installed are 180, with 121 switches, and the following material has been used:—1,800 yards Stannos single, 1/18 and 3/20, 50 yards main cables, 2,500 O.S. clips, 300 continuity fixtures, and fittings for Kalkos boxes and Kalkos tubes, &c.

In addition to the lighting, there is a system of electric fire and burglar alarms worked from the 100-volt accumulators, which are used for the lift control. The wires leading from the accumulators run through fuses to the whole of the bells terminating at a relay. This portion of the wiring is also carried out with Stannos wire, but the wiring between the relay and the whole of the fire and burglar alarm points is ordinary high-class bell wire. The bells which are used for timing (rung three times daily), together with the relay, batteries, &c., are the same as are used for the burglar and fire alarm system, thus ensuring their working condition.

It may be mentioned also that the installation also includes an electric lift, supplied by Messrs. F. G. Childs & Co., Ltd., which is of special interest, because, although the motor is single phase, the control gear is worked by direct current from a Hart accumulator. In order to charge this battery a 5-cell 2-ampere aluminium rectifier is employed.

THE WELSBACH METAL FILAMENT LAMP: ACTION BY GENERAL ELECTRIC CO.

IN the Clerkenwell Police Court on Saturday, Mr. Bros sat to hear twelve summonses taken out by the Wolfram (Tungsten) Metal Filament Lamps, Ltd., and the General Electric Co., Ltd., against the Welsbach Incandescent Gas Light Co., Ltd., for applying a false trade description to the metal filament lamps which they have recently put upon the market. Mr. Rufus Isaacs, K.C., M.P., Mr. H. A. Colefax, and Mr. E. Lunge appeared for the prosecutors, and Mr. A. J. Walter, K.C., and Mr. A. H. Bodkin for the Welsbach Co.

At the commencement of proceedings, Mr. Walter, K.C., for the defendants, said they proposed the case should be tried by jury.

In opening the case, Mr. Rufus Isaacs, K.C., said that there were twelve summonses in all, nine being against the Welsbach Company and three against the managing director of the company, Mr. Lee Fletcher. He proposed, however, to allow the latter summonses to stand over for the present. The summonses were under the Merchandise and Trades Marks Act, 1887, and charged the company with applying a false description to their metal filament electric lamps, and selling and having in their possession lamps to which this false description was applied. The acts complained of related to three specific dates, viz., September 22nd and 29th, and October 8th of this year. In giving the history of the facts of the case, counsel pointed out that the Welsbach Incandescent Gas Light Co., Ltd., was a company incorporated for the purpose of dealing with the invention of Baron von Welsbach (whose full name was Baron Auer von Welsbach), commonly known as the incandescent gas mantle. The company's connection with Baron Welsbach was entirely in relation to gas lighting, and had nothing whatever to do with electric lighting. Consequently these summonses did not relate to the company's gas business. Baron Welsbach's electric lamp patents were acquired by a German company, Deutsche Gasglühlicht Aktiengesellschaft, which was known as the "Auer" Company. This company duly acquired the Baron's patent for the use of osmium in connection with metal filament lamps. This was never in any way acquired by the Welsbach Incandescent Gas Light Co. The "Auer" Company appointed the General Electric Co. as the exclusive agents for the sale of this lamp in this country. After a little while there was a further invention, which could certainly be described as of greater practical and commercial utility. This consisted, among other things, of using wolfram or tungsten as the material of which the filaments of the lamps were made, it being a cheaper and a commoner kind of metal. The "Osram" lamp was made of wolfram or tungsten, and was made under a patent owned by the "Auer" Company, with which Baron Welsbach and the Welsbach Incandescent Gas Light Co. had nothing whatever to do. The General Electric Co. continued to act as sole agents here, but under the new Patents Act it became necessary to manufacture the lamps in this country, and consequently the Wolfram (Tungsten) Metal Filament Lamps, Ltd., was formed for this purpose. There were two facts to be established from this: first, that the Osram lamp was not the invention of Baron Welsbach; secondly, that the Welsbach Incandescent Gas Light Co. had nothing to do either with Baron Welsbach or the "Auer" Company, in relation to electric lamps.

In this state of things, on Wednesday, September 22nd last, there appeared a full-page advertisement in *The Daily Telegraph*, and it was repeated on subsequent days in *The Daily Mail* and other daily papers,* which contained a picture of a metal filament lamp upon which were the words "Welsbach Aur." Then came the following words, to which he attached the greatest importance:—"Remember—that the electric metallic filament lamp was invented by Baron Welsbach, and see that the trade mark "Aur" appears on every lamp." This statement was calculated to lead persons to believe that the lamp which the Welsbach Co. was offering was a lamp which had either been invented or manufactured by Baron Welsbach or the "Auer" Company, which was always associated with Baron Welsbach's inventions, and added strength was given to it by the words, "and see that the trade mark 'Aur' appears on every lamp." In point of fact, the electric lamp which the Welsbach Co. were offering, and which had been sold here, was not invented or manufactured by Baron Welsbach, and it had nothing whatever to do with him or the "Auer" Company.

As a result of the appearance of the advertisements referred to, a representative of the General Electric Co. purchased the lamps on two occasions from the Welsbach Co., and was assured that they were Baron Welsbach's lamps, and the invoices contained the same statement. He would call evidence to show that the defendants had applied a trade description to these lamps which was a false description in a material sense. Certainly the word "Aur" was a trade mark which the Welsbach Co. had used, but whether they had or had not the right to use it in connection with electric lamps, he submitted that the present circumstances were provided for in the Merchandise and Trade Marks Act, and it could not be a defence to the offence which the Welsbach Co. was now charged with, to say that the word "Aur" was on the register of trade marks in their name. No doubt it would be a great advantage to the Welsbach Co. if they could claim such a trade name, and he suggested that the only use for its introduction was to lead the public to think that they were getting lamps invented by Baron Welsbach. As a matter of fact, the materials used in this lamp were entirely different to the materials used in the Osram lamp. Another fact was that before the Osram lamps were actually manufactured in England, they bore the words "Auer Gesellschaft," and this name was certainly associated in the minds of the purchasing public with the original "Auer" lamps made by the "Auer" Company.

In a discussion as to procedure, Mr. Walter said he should urge that there was no case. Mr. Isaacs said of course his learned friend would say this, but he had better hear the evidence first.

The hearing was then adjourned until Saturday next.

THE ELECTRIC DRIVING OF PRINTING PRESSES

THE hearing of the action brought by Messrs. J. H. Holmes & Co. against the Associated Newspapers, Ltd., for alleged infringement of the Clatworthy patent for the electric driving of printing presses, was concluded on Thursday last. On Tuesday Mr. Justice Neville gave judgment, dismissing the action on the ground that the patent was invalid. An abstract of the patent in question and a report of the first three days' proceedings were given on page 915 of our issue of last week.

It will be remembered that Messrs. J. H. Holmes & Co. claimed that the "Kohler" equipments installed for the Associated Newspapers, Ltd., infringed three claims of the Clatworthy patent covering the use of an auxiliary motor connected to the main motor shaft through worm gearing for starting up and running at a slow speed, and a free-wheel clutch so that the main motor can overrun the auxiliary motor. The defendants asserted that the first two claims were invalid on account of anticipation and lack of subject-matter, and denied having infringed the other claim, which is for a hand-operated switch to start the two motors in succession. Abstracts of the five previous patents put forward as anticipations were given in last week's issue of ELECTRICAL ENGINEERING. With respect to the American patent for an electrically operated gun turret granted to G. W. Dickie, it should be noted that only the claims and the figure were published in this country before the Clatworthy patent was applied for. The complete specification, which refers to the use of the auxiliary motor for putting the turret in motion and the subsequent overrunning of the auxiliary motor by the large motor, was only published in this country at a later date. Consequently, it has been argued by counsel that that particular use of the combination could not be taken as common knowledge previous to the date of Clatworthy's patent, as neither the figure nor the claims indicated such use. Further, the small motor was to be switched off at the same time as the large motor was switched in, and not, as in the Clatworthy arrangement, when the large motor had, by virtue of its own torque, overrun the small motor.

Wednesday's proceedings commenced with the examination of Mr. Swinburne, F.R.S., by Mr. Astbury, K.C. Mr. Swinburne stated that there was no advantage gained by driving through the main motor shaft; a parallel drive with the two motors geared separately to the press shaft would do equally as well, as in the latter case also the main motor would be in motion before it was supplied with current. The compound winding mentioned as being provided on the main motor of the Chicago machine described in the *Western Electrician* might, he said, be only for avoiding an excessive current at the lower speeds, and did not necessarily indicate that the main motor was used for starting up. Cross-examined by Mr. Walter with reference to claim 4, witness agreed that there might be invention in combining the switches of the two motors to give overlapping of power in a definite sequence. The next witness called was Prof. C. Vernon Boys, who, in answer to Mr. Astbury, stated that he thought the arrangement described in claim 1 of the Clatworthy patent could not be materially distinguished from that of the Chicago machine described in the *Western Electrician*. He also supported Mr. Swinburne in his view of the series drive. The use of the clutch and the cutting-out device for the small motor was, he thought, anticipated by the previous patents and machines. The Clatworthy invention, if anything, was the arrangement of the motor rheostats so that the main motor could not be switched on before the small motor was running at its maximum speed. Mr. H. V. Hopwood, an assistant librarian at the Patent Office; Mr. J. J. Bland, chief engineer at the *Times* printing office; and Mr. J. C. Holmes, chief engineer at the *Morning Post* office, also gave evidence. After this, Mr. Astbury addressed Mr. Justice Neville on behalf of the defendants, and was followed on Thursday by Mr. Walter, who made his final statement on behalf of the plaintiffs.

In delivering judgment on Tuesday, Mr. Justice Nevill dealt first with the descriptions in the *Western Electrician* and *Electrical Engineer* (N.Y.), of the Chicago printing press, which were published before the plaintiff's patent. He said that as he read this it related to a press driven by two motors, a small one for starting and a main motor overrunning and automatically cutting out the auxiliary motor. Both motors were operated by separate electrical control. The only noticeable differences between the American system and the Clatworthy patent were that in the American machine the two motors were mechanically connected in parallel, whilst in the Clatworthy system they were connected in series, and there was also a different method of control. A good deal turned on the question of whether the mechanical connection of the motors in parallel or series was material. The plaintiffs in this action said it was, as by so doing back-lash of the mechanical gear was avoided. He had come to the conclusion on the evidence, however, that no appreciable back-lash could be caused in the American machine, and that the arrangement of the motors in parallel or in series was not a matter of mechanical importance but a matter of convenience with regard to floor space. The question then arose whether Claim 1 of the Clatworthy patent was a new claim. As he read this, it was not confined to the use of an auxiliary motor in addition to driving by power gear through the shaft of the main motor for the purpose of the claim, in connection with plaintiff's controlling device alone, but in connection with any suitable electrical device for operating motors. It appeared to him that the claim so construed covered the use of motors as described in the American machine in every particular except with regard to the mechanical connection. But he had already held that this was immaterial, and he thought, therefore, that Claim 1 had been anticipated by the published description in this country of the American system. Therefore the plaintiff's patent was invalid, and this action for infringement failed. He dismissed the action with costs, and expressed no opinion on the other points raised in the case.

STREET LIGHTING IN THE CITY OF LONDON

AT the weekly meeting of the Court of Common Council on Thursday, a recommendation of the Streets Committee, authorising that Committee to arrange for further experimental lighting in the City was confirmed. We understand that the Streets Committee have a perfectly free hand in the nature of the experimental lighting to be arranged for, and that it will not confine itself exclusively to either electricity or gas. In our issue for July 15th last, page 645, we gave the contents of a report by a Deputation appointed by the Streets Committee, which visited the principal towns on the Continent, and although the general trend of opinion in that report was in favour of gas lighting, the Committee were not unanimous, and for this reason, before any drastic alterations in the general lighting of the city are recommended, further experiments are to be undertaken. If this question is approached in a perfectly disinterested and broad-minded spirit, there is little doubt that electric lighting will be able to demonstrate its advantages over gas lighting.

WIRELESS TELEGRAPH NOTES

A report on the working of the Trinidad-Tobago wireless station shows that ships were communicated with at a distance of from 15 to 240 miles, while on one occasion the station got into touch with the German cruiser *Bremen* at a distance of 400 miles. Working expenses were £907, of which £674 is accounted for under salaries. The system dealt with 545 private, and 200 official messages, and, in addition, some 500 words per day were transmitted to Tobago.

A wireless telegraph station is being installed at Stancliff Moor, Darley Dale, Derbyshire. There are two 60-ft. poles, and the Balsillie system is being employed. The work is being carried out by the British Radio Telephone & Telegraph Co., of London. The site chosen is almost in the centre of England, and is 1,000 ft. above sea-level. Communication with the Continent is contemplated, and, owing to the height of the site chosen, it is not anticipated that there will be any interference with the Admiralty or the coast stations.

The Australian Postmaster-General has called for tenders by April next for the erection of wireless telegraph stations on North and South Head, Sydney, and on Fremantle heights. Tenders are to be delivered by February 22nd, and must comply with the conditions of the British Radio Telegraph convention, and each installation must have a radius of 1,000 miles.

The *Standard* correspondent at Cape Town states that it is understood the Government have practically decided to establish wireless telegraph stations at Cape Town and Port Elizabeth, each having a radius of 450 miles. It is hoped that the Natal Government will arrange that the proposed station at Durban shall have the same radius, and thus complete the chain round the coast from Port Nolloth to Delagoa Bay.

The American army transport *Bulford*, which arrived at Manila on October 6th, reported, says *The Electrical World*, that wireless messages were exchanged with the Pacific coast over a distance of 3,500 miles.

Standard Threads for Sparking Plugs.—The Engineering Standards Committee have issued a Report (No. 45) on standard dimensions for the threads of sparking plugs for internal combustion engines. The thread chosen is the ¾-in. diameter thread, with seventeen threads to the inch, originated by Messrs. de Dion-Bouton, and in universal use. The Committee, however, point out that the small diameter of this thread does not give sufficient space for the internal portions of the plug without rendering the walls somewhat thin, and they propose to hold a conference with the Royal Automobile Club and the Institution of Automobile Engineers with a view to establishing an alternative standard of larger diameter. The price of the specification is 2s. 8d., post free, and it may be procured from any bookseller or direct from the offices of the Committee, 28 Victoria Street, Westminster. It is published for the Committee by Messrs. Crosby Lockwood & Son, 7 Stationers' Hall Court, Ludgate Hill, E.C., and 121A Victoria Street, S.W.

ROYAL OPENING OF A CANADIAN INSTITUTE BY CABLE

BY means of a special arrangement of automatic relays, the King was enabled personally to open the new Tuberculosis Institute at Belmont Park, Montreal, on Thursday last, by pressing a button arranged for the purpose in a room at West Dean Park, near Chichester, where his Majesty was then staying. The distance between the two buildings is some 3,000 miles, but by means of a current transmitted and automatically relayed over land lines and one of the Atlantic cables, the King was able to work a relay at the Institute. This relay automatically brought into operation an electrically driven mechanism which caused the doors of the Institute to be thrown open, the electric lamps to be switched on, and the national flag to be hoisted on the building.

Two special wires were put up by the Post Office authorities between West Dean Park and Chichester Post Office; one was used for the relay current and the other for special messages. From the Chichester Post Office the line was as follows:—Chichester to the General Post Office, and from there to the Royal Exchange office of the Commercial Cable Co.; from this office the relay current and the messages, respectively, were transmitted to the Waterville Island cable station, and from there over one of the company's five cables to Canso, Nova Scotia; at this point a telegraph line of the Canadian Pacific Railway Co. was connected, and the circuit was completed by a temporary line from Montreal to the Institute. The current impulse to operate the motor mechanism was automatically relayed over the whole circuit without manual retransmission even over the cable, but the message declaring the Institute open and the various congratulatory messages were retransmitted at the cable stations in the usual manner. The ceremony was fixed to take place at four o'clock Montreal time, corresponding with nine o'clock Chichester time. Shortly before the appointed time, the land lines and the cable concerned were cleared, and a test current was transmitted to ensure that the circuit was complete. In less than twenty seconds from the time of the transmission of the Royal signal, an answering signal was returned indicating the successful operation of the mechanism. Mr. F. Ward, the engineer and manager of the Commercial Cable Co., and the other authorities responsible for the arrangements, are to be congratulated for having carried out such a difficult piece of work so successfully.

THE DEVELOPMENT OF ELECTRIC SUPPLY

MR. S. J. WATSON (Borough Electrical Engineer, Bury) gave his inaugural address as Chairman of the Manchester Section of the Institution of Electrical Engineers on Friday last. After one or two remarks as to the Institution in general, he proceeded to the main subject of his address, which was a survey of various points of interest in connection with the development of electric supply undertakings during the past 15 years. Giving a table of statistics, he showed how the amount of capital invested has increased from four to nearly sixty millions of money in 15 years, and traced the increase in supply during each period of five years, and the extra cost of dealing with such increase. In the case of his own undertaking, for example, during the last seven years, the output had increased nearly tenfold, and large extensions had been carried out. The extra generating costs amounted to 0·293d. per unit, the extra capital charges on plant to 0·154d. per unit, the extra distributing costs to 0·234d. per unit, and the extra management charges to 0·087d. per unit, so that the total additional cost of supplying the extra units amounted to 0·768d. per unit. The load-factor of the increased output had been 23·2 per cent. The average capital cost per kw. of plant and mains installed had decreased from £139 in 1894 to £72 in 1909; the number of units sold per £1 of capital invested had increased from 3·4 to 14·2; the average price charged had been reduced from 6·16d. to 2·16d. per unit; and the gross profit had gone up from 3·3 per cent. to 6·6 per cent. Also, whereas the cost of the plant and mains added during the period 1894 to 1899 was £92 per kw., the cost of the additions during the period 1904 to 1909 was only £57 per kw., and the additional working expenses for the increase in the output between 1894 and 1899 was 2·13d. per unit, while the cost for the increase in output between 1904 and 1909 was only 0·68d. per unit. He pointed out that there was a difference of 293,095 kw. between the total capacity of the plant installed and the maximum load recorded—that is to say, that no less than 37 per cent. of the total plant was provided as spare. This represented a capital expenditure of over six millions which was entirely unproductive, a figure which, he thought, could have been considerably diminished by the greater adoption of interconnection. The reductions in average cost per unit were due to a variety of causes, not the least among which had been the increase in the size of generating sets.

In passing on to speak of the latest developments in steam-turbine plant, Mr. Watson said that it appeared to be a sign of the times that the impulse machine was being used to an increasing extent in the large sizes. The tendency of turbine construction was to increase the clearances, reduce the number of stages, and to shorten the length between bearings, and progress along these lines was likely to be more successful with the impulse than with the reaction engine.

With regard to exhaust-steam turbines, he was of opinion that for public generating stations the circumstances would have to be exceptional to result in any ultimate advantage from installing exhaust or mixed-pressure turbines, as compared with high-pressure turbines of equal capacity. In the latter case the first cost would be slightly more, but the steam consumption would be less. He suggested, however, that, to obtain the highest possible efficiency from the use of highly superheated high-pressure steam in large units of plant, a combination might be used consisting of a one- or two-stage impulse turbine at the high-pressure end, a reciprocating engine for the intermediate pressure, and an exhaust turbine at the vacuum end. The question of gas plant for generating stations was principally one of load-factor. For a direct-current station situated in a good position for obtaining coal supplies, a combination of gas-engines as the prime movers with large storage battery capacity appeared to be an excellent arrangement. The Chairman then passed on to a few remarks on the prevailing tendencies in transmission and distribution systems, developments in accessories, lamps, &c., and the benefits obtained by the increase in motor hiring, &c., a matter where, in his opinion, municipal and company undertakings ought to be on an equal footing.

In conclusion, Mr. Watson reviewed one or two aspects of the question of charging systems, dwelling more particularly on the desirability of taking into account the differences in the capital expenditure on mains necessitated for customers at different distances from the power stations, and the fact that the meter reading and office expenses in connection with a customer are independent of his consumption. Speaking generally of rates for power supply, he expressed the view that the figure of 0·3d. per unit sometimes given as the price above which it would not pay a manufacturer in Lancashire to enter into a contract for a supply of power was too low. Many large manufacturing concerns had found it remunerative in the long run to purchase from outside sources at prices varying between 0·75d. and 0·50d. per unit, and such a price was quite sufficient to enable the most of the larger undertakings to maintain and even improve their financial position, as with the access of the power load at these low prices the working expenses per unit were very largely reduced.

NEW FLAME ARC LAMPS

TWO new flame arc lamps have just been placed on the market by the Globe Electric Co., Ltd. (11 Farringdon Avenue, London, E.C.). These are named respectively the "Santoni-Standard" lamp and the "Santoni-Kosmos" lamp. The latter is especially suitable for street lighting, and both lamps are to be obtained with mechanisms respectively adapted to work with direct-current and alternating-current.

The "Santoni-Standard" is a converging carbon lamp, burning "Noris-Excello" metal-cored flame carbons, and is made in two sizes. The small size has an overall length of 2 ft. 9 in., takes 16 in. carbons, and gives 8 to 10 burning hours, while the large size, with an overall length of 3 ft. 3 in., takes 24 in. carbons and gives 16 to 18 burning hours. In the case of the direct-current lamp the mechanism comprises a single pulley, over which passes the woven copper cord for supporting the weighted carbon holders. This pulley is attached to a train of wheels, the star-wheel of which engages with a detent fixed to a rocking frame. Attached to the frame at opposite ends are two armatures which float over the poles of the series, and shunt magnets respectively. The vertical lever for adjusting the position of the swinging carbon is also attached to the frame, the movements of the system being controlled by a dash-pot and a spring. In the alternating-current mechanism the detent engaging the star-wheel is fixed to a pivotted lever. This lever is attached at one end to the plunger of a solenoid, comprising both a shunt and a series coil, and at the other end to the dash-pot. The economiser of the "Santoni Standard" lamp is of cast iron. In both the D.-C. and the A.-C. types an automatic carbon switch is provided for breaking the shunt circuit when the carbons are entirely burnt out. The mechanism is covered with a zinc-lined cap, and a cast-iron ring supports the globe. The latter has an ash-tray and ventilator at the bottom, and a strong current of air up the inner surface of the globe to the outlets round the ring support effectually prevents the formation of any deposit. All the parts, including the mechanism, appear to be of a very substantial nature, capable of lasting and of withstanding rough usage in unskilled hands. These lamps take from 6 to 15 amperes, the voltage across the lamp being from 45 to 47 volts.

Digitized by Google

The "Santoni-Kosmos" lamp is a vertical carbon flame lamp especially suitable for street lighting. The voltage across the arc is only from 30 to 33 volts, and so on. Six lamps can be run in series on 220-volt circuits, or fourteen on 500-volt circuits. This lamp is made in three sizes, 2 ft. 5 in., 2 ft. 9 in., and 3 ft. 1 in. long respectively. The corresponding burning hours are 13, 18, and 24 hours for the D.-C. type, and 10, 13, and 17 hours for the A.-C. type. The D.-C. lamp takes from 8 to 12 amps., and the A.-C. lamp from 10 to 15 amps. As in the case of the "Santoni-Standard" lamp, there are two types of mechanism. In the A.-C. type the copper cord passes over a pulley on the clockwork, the whole being pivotted and rocked by the motion of the regulating lever. The detent is fixed, and the rocking of the gear before the star-wheel leaves the detent gives the necessary adjustment of the carbons, which in this lamp are vertically one above the other. In the D.-C. mechanism the clockwork and the pulley are rigidly attached to a rocking frame carrying the two armatures similar to that of the "Santoni-Standard" lamp. The other details, including the shunt cut-out, are the same in both patterns. In the vertical carbon lamps the lower carbon holder is fixed by a ball joint which enables accurate alignment of the carbons to be obtained.

The Globe Electric Co. will shortly bring out a double-carbon flame arc lamp. This will be constructed in two sizes with 20 and 38 burning hours respectively. It may also be mentioned that this firm is the London agent of the North-Western Electrical Appliance Co., of Glasgow, and has a large stock of that firm's specialities. These include arc-lamp lowering gear, contact suspension devices, winches, span-wire gear for centrally hung lamps in streets, and many patterns of pillars and carriers.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

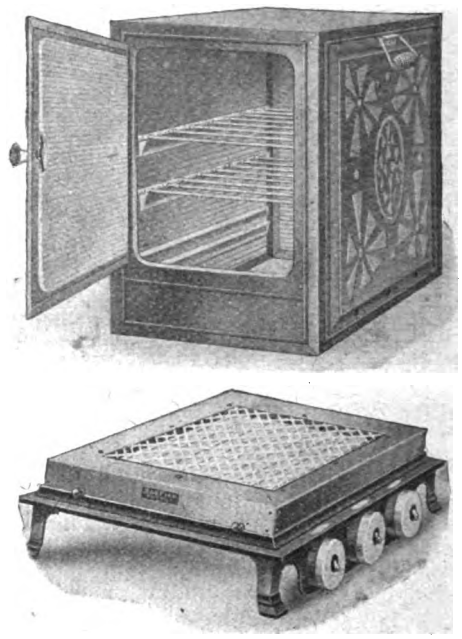
METAL FILAMENT LAMPS.—A small pamphlet which Mr. G. Braulik is distributing in large numbers gives particulars of the "Eclipse" metal filament lamp, which is made in a number of sizes for various voltages, ranging from the little 5 c.p. 25 lamp to a 250 c.p. lamp for 225/250 volts. The bulbs of the ordinary sizes are no larger than those of the ordinary carbon filament lamp, so that special shades are not called for.

ELECTRIC HEATER.—A very large number of electric heaters, both of the convection and radiator types, are contained in a new catalogue of "Eclipse" electric heaters issued by the Electric and Ordnance Accessories Co., Ltd., Cheston Road, Aston, Birmingham. These include ornamental heaters in various styles—a neat circular pattern for halls, offices, &c., wall-type heaters, car heaters, factory and workshop heaters. In addition to the full catalogue, a small folder is issued which can be printed with contractors' names.

METAL FILAMENT LAMPS.—The Electric and Ordnance Accessories Co., Ltd., are also issuing a small folder giving particulars of the E.O.A. metal filament lamp, which is made from 16 to 100 c.p. for 60/135 volts, from 25 to 100 c.p. for 140/160 volts, and from 32 to 100 c.p. for 200/260 volts. 25- and 50-volt lamps are also made. The larger lamps can be had in spherical as well as pear-shaped bulbs. An efficiency of 1·1 watt per candle is claimed, and an average life of 1,000 hours.

CRANES AND HOISTS.—A new catalogue dealing with cranes and hoists of all kinds, and operated by electric, hydraulic, and hand power, has been issued by Messrs. R. Waygood & Co., Ltd. (Falmouth Road, London, S.E.). The catalogue is illustrated with a number of photographs of crane installations carried out by the firm, including a three-motor, two-ton, electric gantry crane on Tower Bridge Wharf, London, which has a patent double luffing system, with a compensating balance to reduce the power required.

ARC LAMPS.—A post-card which is being circulated by Messrs. Veritys Ltd. (31 King Street, Covent Garden, W.C.) gives particulars of the "Comet" shuntless enclosed arc lamp for both D.-C. and A.-C. circuits. The lamp is made in two sizes taking 3-4 and 5 amps. respectively, and burns two in series on 150 to 250 volt circuits. The burning hours are 60 and 95 hours respectively.



OIL SEPARATORS.—A pamphlet is to hand from Messrs. Lassen & Hjort (52 Queen Victoria Street, London, E.C.) describing an exhaust steam oil separator, the patent rights of which for Great Britain have been acquired by them. This apparatus, which is known as the "Turbo Oil Separator," works on a principle similar to the cream separator, and is rotated by the remaining energy in the steam, or is, if necessary, power-driven. We understand that over 300 plants have been installed within the two years this apparatus has been on the market, and that one colliery firm alone has purchased fifty.

Electro Harmonic Society.—The following are the arrangements of the Electro Harmonic Society:—Monday, November 15th, Ladies' Night; Friday, December 15th, Smoking Concert; Friday, January 7th, Smoking Concert; Tuesday, February 15th, Ladies' Night; Friday March 4th, Smoking Concert.

NEW HEATING AND COOKING APPARATUS

SEVERAL new developments of the Bastian electric heater, which was described in ELECTRICAL ENGINEERING of July 8th, 1909, page 631, have just been placed on the market. The original form comprises a group of horizontal quartz tubes or glowers, each of which contains a spiral of nickel wire, arranged in a supporting frame. The resistance of the spirals is such that the glowers and the spirals within them are brought to a bright red heat within fifteen seconds of the current being switched on. The use of the quartz tubes renders a high temperature possible, and considerably increases the radiating power of the device. Each of the quartz tubes is about 12 in. long by $\frac{3}{8}$ in. diameter. They are held in metal clips, the tightening screws of which have an additional nut and act as terminals for the ends of the resistance spirals, and the metal clips slip into spring contact pieces. The resistance spirals have a life of from 1,000 to 2,000 hours, as the oxidation is very slight, but when they do burn out they are easily replaced, and cost only 6d. each.

Most of the new patterns include an aluminium frame with six or eight quartz tubes and one or two switch connections. Such a frame weighs only 1¾ lb. complete, and consumes 750 watts with the switches in the full-on position. This frame is the standard unit, and can be placed in any suitable design of casing, either for a radiator or for cooking apparatus.

COMBINED HOT-PLATE AND OVEN.

The oven above is fitted with a similar frame, but with a cast-iron base containing a set of quartz tubes taking from 400 to 1,500 watts, and a light copper cover with readily removable grids. The heater itself is mounted in a strong cast-iron base, and can be used with a frying-pan or kettle or to make toast. Switches to give three degrees of heat are provided. The oven is 18 in. high, 12 in. deep, and 13½ in. in breadth; it weighs only 9 lbs.

These heaters and cooking appliances are now being sold by a number of licensees, including Messrs. Drake & Gorham, Ltd. (66 Victoria Street, S.W.). Messrs. Gillespie and Beales exhibited a number of forms of these ovens and radiators at the recent Hampstead Electrical Exhibition.

Tramway Rating.—The Blackpool & Fleetwood Tramroad Company have not yet settled their difference with the local authorities as to whether their undertaking is a tramway or a railway for the purposes of rating. It has already been held by the House of Lords that so far as the line is on private property it must be treated as a railway, and rated at a quarter the full rateable value. A dispute has now arisen with the Fleetwood Urban District Council concerning the five furlongs of tramway, the Company claiming to be assessed at a quarter the rateable value, in the same way as the tramroad portion. At the Preston Quarter Sessions last week, the Company appealed against the full assessment, but for the Council it was urged that if the Company could claim exemption for this line, then every tramway in this country could claim to be a railway in the same way. The Chairman said he would consider his decision, and give it on November 29th. He said he anticipated that leave to appeal would be asked for whichever way the decision went, and the parties could take it that leave to appeal would be granted.

LOCAL NOTES

ACTON: *Charges for Electricity.*—The Electrical Engineer recommends the adoption of a charge of £5 per kilowatt of maximum demand per annum, plus 1d. per unit for all power users, and a flat rate of 2d. per unit for heating purposes.

ARGENTINE: *Buenos Ayres: The Telephone System.*—The *Review of the River Plate* states that a report upon the telephone system of the city has been prepared. It appears that there are two companies, neither of whom have a regular concession, but work upon permits. The only contribution made by the companies to the revenue of the Corporation is a small annual charge for each of the posts in the streets, but as the lines are being gradually placed underground this revenue is becoming annually less. It is suggested that concessions should be granted to the companies for 60 years.

AYR: *Electricity Accounts.*—The accounts of the Electricity Department for the year to May 15th shows a gross profit of £7,033, and after meeting interest and sinking fund, there is a net surplus of £1,424. The number of units sold was 1,444,469, an increase of 69,277 over the previous year. The coal consumption has decreased considerably, owing to the installation of the feed water purifying plant installed last year.

BECKENHAM: *Electric Wiring.*—With reference to the suggestion of the Maidstone Corporation that municipalities not in possession of electric wiring powers should undertake the promotion of a Bill in Parliament to secure these, the Council have declined to join in this undertaking for the reason that they do not think there is any prospect of such a Bill passing.

BELFAST: *Tramway Poles.*—A report has been prepared by the Tramways Manager and the Electrical Engineer in favour of the transfer of the centre tramway poles of the city to the sides of the streets. This change is recommended both in the interests of the ordinary street traffic and economy. The estimated cost of removing all the centre poles is put at £1,988. Consideration of the report has been deferred until the next meeting of the Tramways and Electricity Committee.

BRADFORD: *Electricity Undertaking.*—Mr. T. Roles, the City Electrical Engineer, reports that it was impossible to complete the extensions of the generating plant at Valley Road Works by the end of August, as was anticipated. He expected, however, that the first turbine will be in operation in a few weeks' time, but the second one a month later. In speaking upon the effect of metal filament lamps, Mr. Roles expresses the opinion that the 25-c.p. lamp will permanently take the place of the old 16-c.p. carbon lamp. In view of the still further use of metal-filament lamps, Mr. Roles states that it is doubtful whether the increase in the number of consumers will make up for the loss of consumption which must result. He, therefore, advocates giving their encouragement to power uses and to the use of electricity in other directions than lighting.

BRIGHTON: *Railless Electric Traction.*—The Tramways Committee recommend the Municipal Tramways Association to urge the Board of Trade to obtain Parliamentary powers to enable the department to issue provisional orders enabling tramway authorities to use the trackless trolley system.

DUNDEE: *Street Lighting.*—The Town Council, after consideration of the relative merits of electricity and gas, and also of reports by the engineers on the subject, have unanimously agreed that High Street, Lochee, shall be illuminated by electricity.

EDINBURGH: *Electric Lighting Accounts.*—The accounts of the electric lighting department for the year to May 15th, 1909, shows an expenditure of £66,118, and a revenue of £127,853. After meeting capital charges there is a balance of £2,072. It will be remembered that the Electricity Committee decided to deal with the accumulated balance of £10.541 by transferring £9.794 to relief of rates, and carry £747 to reserve fund. The total number of units sold was 15,255,465, against 14,847,008 in the previous year.

KINGSTON-ON-THAMES: *Electricity Accounts.*—The annual report of the Borough Electrical Engineer, Mr. J. E. Edgcome, says *The Times*, reports an increase of 82 consumers and 5,734 8-c.p. lamps, &c., which is "the largest increase in any one year since the beginning of the undertaking." The deficit on the year's working, however, is £1,251 13s., compared with £884 15s. last year. The total capital outlay now stands at £103,429 8s. 7d., of which £29,453 16s. has been repaid, and there are 1,106 consumers with connections equal to 50,963 lamps of eight candle power, the electricity supplied to them being 568,749 units. During the 15 years the undertaking has been run by the Corporation, the net loss to the ratepayers has amounted to £12,378.

LONDON: *London County Council: Harrow Road Tramways.*—The County Council have completed the purchase of the Harrow Road and Paddington tramways from the Metropolitan Electric Tramways, Ltd. The agreement for the temporary working of the lines by the company has been exchanged.

Railless Electric Traction.—With reference to the suggestion by the Highways Committee last year that powers should be sought for running a service of trolley 'buses in the Blackwall and Rotherhithe tunnels, further consideration has now been given to this matter. As a consequence, the Highways Committee have come to the conclusion that the system is still in the experimental stage, and they recommend that no further action be taken at present.

County of London Company's Mains.—The proposal of the County of London Electric Supply Co., Ltd., to lay three 2½-in. iron conduits across London Bridge, and through the City, for the purpose of linking up their Wandsworth and City Road stations, has been disapproved of by the City Corporation, mainly owing to the interference with traffic which the laying of these conduits will necessitate. It will now rest with the Corporation to suggest an alternative route, or means of carrying out the same work, and unless the Company and the Corporation can agree, the matter will have to be referred to the Board of Trade for arbitration. The London County Council, who, under the Act, have a voice in the matter, have also disapproved of the proposed work.

NORWICH: *Street Lighting.*—The following resolution was passed at the last meeting of the Corporation:—(*a*) The Council approves of the principle of substituting electricity in the place of gas for the public lighting of the city. (*b*) That the Executive and the Electricity Committees be authorised to confer and to prepare a scheme for submission to the Council for carrying the proposal into effect at the expiration of the existing contract with the British Gas Light Co., Ltd.

Tramways.—In view of complaints from the ratepayers, of the service provided by the Norwich Electric Tramways Co., the Corporation recently appointed a committee to confer with the company in connection with the matter. Conferences have taken place between this committee and the company, in consequence of which the latter have agreed to make certain re-arrangements and alterations in the service with a view to meeting the objections raised. They have also agreed to install automatic signals at various points, but refuse to modify the present fare system or introduce ½d. fares. On the whole, the committee report that the company have shown a generous disposition to meet the wishes expressed by the committee.

OLDHAM: *Charge for Tramway Energy.*—The Electricity Committee have offered to reduce the charge for electricity to the Tramways Committee from 1½d. to 1¼d. per unit.

SHEFFIELD: *Electrical Exhibition.*—An exhibition of electric lighting and heating apparatus has been opened by the Corporation Electricity Department at 9 Fargate. The apparatus shown includes water-heaters, ovens, irons, kettles, coffee-pots, vibrators, hair-dryers, drills and all the latest electrical apparatus for domestic use.

WILLESDEN: *Charging for Electric Supply.*—Interviews have taken place between representatives of the Council and the North Metropolitan Electric Power Supply Co. with reference to the terms under which the Council are to receive bulk supply from the company from February, 1911. All matters had been previously settled except as to metering the maximum demand. It has now been agreed, as formerly suggested, that the maximum demand shall be indicated by a demand indicator so constructed as to indicate the simultaneous maximum demand of the a.c. and d.c. supply. As we have already notified, the terms are to be £1 per quarter per kw. of maximum demand, plus £1,000 per quarter for the 400,000 units per quarter. Further units will be charged at 0·04d. per unit.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AMBLE.—Mr. C. A. Esmarch, of Newcastle-upon-Tyne, has been instructed to prepare a report upon an electric lighting scheme.

AUSTRIA-HUNGARY.—The *Società Adriatica d'Elettricità* has been formed in Fiume, for the purpose of erecting a central generating station equipped with an installation capable of developing 45,000 to 50,000 h.p., which may, if necessary, be increased to 80,000 h.p. The capital of the company is £1,000,000. The waterfalls of the river Gaska, near Otociac, on the Croatian frontier, are to be made use of.

BRIGHTON.—The Electrical Engineer recommends the installation of a fifth turbo-generator set at the Southwick power house, and also additional transformers.

EASTBOURNE.—Tenders are to be invited for a condensing plant, similar to the one now in use in the generating station. The estimated cost is £1,835.

INDIA.—The Lucknow Municipal Board invite tenders for public lighting by electrical or other means by December 31st. Particulars from the Secretary to the Board.

SHEFFIELD.—Mains are to be extended at an estimated cost of £605.

WALTHAMSTOW.—The Local Government Board has sanctioned the borrowing of £1,100 for feeder cables for interconnecting the Higham Hill and Blackhorse Lane feeders.

Miscellaneous

AUSTRALIA.—Although two invitations have been made to Australian manufacturers to tender for the supply of slot telephone apparatus, no offers have been forthcoming. This is regarded as surprising, as telephone apparatus is actually manufactured in the Commonwealth. The Postmaster-General is endeavouring to find out whether the failure is due to the specification or the fault of the instrument, and whether it is possible to alter either or both of these in order to encourage Australian manufacturers to tender.

BRADFORD.—Tenders are invited by the Tramways Department for miscellaneous stores during the year ending Dec. 31st, 1910, including electric lamps, lamp fittings, and insulating tapes. Particulars from the Tramway offices, 7 Hall Ings, Bradford, and tenders to the Town Clerk, by Nov. 13th.

EPSOM.—The Electricity Department require eight direct-current long-burning flame arc lamps. Particulars from the Electrical Engineer, and tenders to the Clerk by November 2nd.

FIFE.—Extensions of the Fife tramways are contemplated between Lochgelly, Bowhill, and Kinglassie.

ILFORD.—Tenders are invited for 40 flame arc lamps. (See an advertisement this week.)

LIVERPOOL.—An application has been made for a loan of £10.000 for additional tramcars.

SWANSEA.—The Streets Committee have resolved that, whenever electric cables are available for lighting, the Borough Surveyor and the Electrical Engineer are to confer with a view to the substitution of electric for gas lamps.

SWITZERLAND.—Powers have been granted to the St. Gall-Speicher-Trogen Railway Co., of Trogen, for the construction of a single-track, metre-gauge electric railway, 5½ miles long, on the St. Gall-Walzenhausen route, *viâ* Trogen and Heiden, with a branch from Kaien to Rehetobel. The total cost of the work is estimated at 1.075.000 francs (£43.000).

WARRINGTON.—The Electricity and Tramways Committee invite tenders for arc lamp lowering gear. Particulars from, and tenders to, the Borough Electrical Engineer.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—The London County Council invite tenders for the electric wiring of the Buxton Street Elementary School, Whitechapel. Particulars from the Engineer to the Council, and tenders to the Clerk by November 3rd.

Rebuilding bank, corner of Angel Lane and Broadway, Stratford, E., for the directors of the London and Provincial Bank; Head Office, 3 Bank Buildings, Lothbury, E.C.

N.E.—Isolation rooms at Eastern Hospital, Homerton, N.E. Architects, T. W. Aldwinckle & Son, 20 Denman Street, E.C.

Extensions to public library (£1,797), Harlesden. Builders, Sabey & Co., Ltd., St. Peter Street, Islington, N.

N.W.—Police station, corner of Rosslyn Hill and Downshire Hill, Hampstead, N.W. J. Dixon Butler, Surveyor Metropolitan Police, New Scotland Yard, S.W.

PROVINCES.

BRADFORD.—Alterations to Turkish and medicated baths (£1.370). Builders, Toothill & Balmforth, 631 Little Hornton Lane, Bradford.

Conversion of Victoria Hall, Wyke, into baths (£2.200). J. H. Cox, surveyor, Bradford City Council.

BURY ST. EDMUNDS.—Alterations to Town Hall (£1.200). Architect, S. A. Naish, 30 Abbeygate Street, Bury St. Edmunds.

DARLINGTON.—Block of offices. Architects, Hoskins & Brown, Darlington.

DUNDEE.—Additions, poorhouse (£3,000). Architect, T. Cappon, 32 Bank Street, Dundee.

DURHAM.—School, Eldon Lane (£2,500). Architect, F. E. Coates, Shire Hall, Durham.

ECCLES (LANCS.).—Skating rink, Church Street, Eccles Roller Rink Co.

FALMOUTH.—The Workhouse Committee recommend the electric lighting of the workhouse. The matter is to be discussed at the next meeting of the Guardians.

GLASGOW.—Flour mills (£3,000). Architect, H. D. Morton, 170 Bath Street, Glasgow.

HANWELL.—Isolation hospital. Surveyor, S. W. Barnes, Hanwell Urban District Council.

LIVERPOOL.—Business premises (£1,500). Architect, H. Goldsmith, Dale Street, Liverpool.

MEXBOROUGH.—Free library. Architects, Russell & Cooper, 11 Gray's Inn Square, W.C.

MOUNTAIN ASH.—Small-pox hospital. Surveyor, E. Thomas, Mountain Ash.

ST. HELENS.—Additions, Providence Hospital. Architect, J. Barony, St. Helens.

SOUTHAMPTON.—College building, Highfield Court. Governors, Hartley College, Southampton.

WANSTEAD.—School (£3,926). Architect, C. H. Bressey, 70-71 Bishopsgate Street Within, E.C. Builder, W. E. Davey, Ruskin Lodge, Victoria Avenue, Southend.

WILLESDEN.—School (1,000 places), Stonebridge, Willesden. Surveyor, Willesden, U.D.C.

TENDERS RECEIVED AND ACCEPTED

ABERDEEN.—The tender of Messrs. John Blackie & Sons, at £210, has been accepted for the electric lighting installation at the City Hospital.

DEVONPORT DOCKYARD.—The Admiralty have adopted the Davy flame arc lamp for the lighting of Devonport Dockyard. Messrs. Foote & Milne, Ltd., the contractors for the installation, have recently placed an order for forty Davy long-burning lamps with Messrs. Frampton & Paine, who are the agents for Arc Lamps, Ltd., in the eastern, southern and western counties. These lamps, which burn for thirty-six hours with one trimming, are fitted with a device that prevents the fumes settling on the globes, thus ensuring the maximum light throughout the whole of the run.

HERTFORDSHIRE.—The County Council have accepted the tender of Rogers & Gowlett, Ltd., at £138 5s., for substituting metal filament lamps for carbon lamps in five schools with approximately 800 lamps.

LONDON: *London County Council.*—The Highways Committee have accepted the tender of Messrs. Stanley Bros., of Nuneaton, for the supply of 440,000 stoneware ducts at £9 per thousand, and that of Messrs. Reid Bros., London, for the laying of same at £26,622.

The following firms have submitted tenders for high- and low-tension switchgear for the tramways undertaking: Switchgear Co., Ltd., £3,517 4s.; Johnson & Phillips, Ltd., £3.625; Spagnoletti, Ltd., £3,669 18s.; Ferranti, Ltd., £4,111 11s.; Electric Construction Co., Ltd., £4,175 12s.; General Electric Co., Ltd., £4,225 1s.; British Westinghouse Electric & Manufacturing Co., Ltd., £4,864 4s. The tenders of the Switchgear Co., Ltd., is recommended for acceptance.

Tenders have been received as follows for motor-generators: Lancashire Dynamo Motor Co., Ltd., £3,457 10s.; General Electric Co., Ltd., £3.821 10s.; Bruce, Peebles & Co., Ltd., £3,939; Dick, Kerr & Co., Ltd., £4,206; British Electric Plant Co., Ltd., £4,231; British Westinghouse Electric & Manufacturing Co., Ltd., £4,291; Brush Electrical Engineering Co., Ltd., £4,997; Electric Construction Co., Ltd., £5,428. The tender of Messrs. Dick, Kerr & Co., Ltd., is recommended for acceptance.

Southwark.—The Council have accepted the following tenders for motor-generating plant for Kennington Theatre: The General Electric Co., two 40-kw. motor-generators, £398 10s.; switchboard, £37 5s.; Crompton & Co., two 3-kw. motor-generators, £88. This firm's tender for a switchboard was also accepted.

Woolwich.—The Council received the following tenders for the supply of carbons during the next twelve months:—Johnson & Phillips, (*a*) 15.000 pairs "A" quality, £59 18s. 9d.; (*b*) 60.000 pairs oriflamme, £168; (*c*) 1,000 pairs Brockie-Pell, £4; (*d*) 2.000 pairs excello, £27 15s.; (*e*) 16,000 pairs yellow flame alternating, £45. General Electric Co., Ltd., (*a*) £88 10s.; (*b*) £165; (*c*) £4 1s.; (*d*) £21 14s.; (*e*) £45 12s. Oliver Arc Lamp, Ltd. (accepted for *b* and *e*), (*a*) £104 16s. 3d.; (*b*) £165; (*c*) £4 9s. 9d.; (*d*) £20 12s.; (*e*) £45 12s. Ships' Carbons, Ltd., (*a*) £105; (*b*) £173 5s.; (*c*) £4 10s.; (*d*) £20 12s. 6d.; (*e*) £47 17s. 4d. Electric & Ordnance Accessories Co., Ltd., (*a*) £99; (*b*) £184 15s.; (*c*) £4 10s. 3d.; (*d*) £24; (*e*) £48. Crompton & Co., (*a*) £54 11s. 3d.; (*b*) £227 10s.; (*c*) £4 11s. 6d.; (*d*) £21 4s.; (*e*) £67 4s. The Brockie-Pell Arc Lamp, Ltd., (*a*) £60; (*b*) £238 10s.; (*c*) £4 17s. 6d.; (*d*) £26 10s.; (*e*) £70 18s. Sloan Electrical Co., Ltd., (*a*) £105; (*b*) £216 15s.; (*c*) £4 7s.; (*d*) £21; (*e*) £64. Siemens Bros. (accepted for *c* and *d*), (*a*) £91 2s. 6d.; (*b*) £276; (*c*) £4 3s.; (*d*) £16 19s.; (*e*) £69. With regard to *a*, the Council decided, in view of the variation in the amounts of the tenders, which seemed to indicate a great difference in the quality of the carbons offered, to have tests taken of the various samples.

Metropolitan Asylums Board.—The Board have accepted the tenders of W. J. Fryer & Co., £60 10s., for the installation of a 6 h.p. motor at the Mead Ambulance Station, and at £36 6s. for electrical work in the boiler-house, engine-room, and laundry of the South-Western Hospital.

SALFORD.—The Education Committee has accepted the tender of Eckstein, Heap & Co., Salford, at £43 15s., for a main switchboard at the Institute.

WALTHAMSTOW.—The Council have accepted the tender of Henley's Telegraph Works, Ltd., at £690, for feeder cables.

WATFORD.—The Council have accepted the tender of the British Westinghouse Co. for the annual supply of transformers.

Parliamentary.—The following Acts of Parliament received Royal Assent last week:—Edgware and Hampstead Railway Act, 1909; Telegraph (Arbitration) Act, 1909.

The Colinton Tramways Order Confirmation Bill was read a third time in the House of Commons on Friday.

COMPANIES' MEETINGS AND REPORTS

CLEVELAND & DURHAM ELECTRIC POWER CO.—The report for the year to June 30th shows a gross profit of £2,098, but after including the sum brought forward, and providing for debenture and other interest, there is a loss of £3,657. Owing to the depression in trade, the plant installed in consumers' premises has been employed considerably less than has been usual in normal times. The connections to the system now amount to 29,849 h.p., an increase of 9,744 h.p. during the year.

FERRANTI.—The report for the year to June 30th shows a gross profit of £29,218, and a net surplus of £12,239. After transferring £5,000 to depreciation account, and meeting interest on prior lien debentures, first mortgage debentures, and bank loan, there is a balance of £307, which reduces the debit of profit and loss account to £1,829.

DRAKE & GORHAM.—At the annual general meeting last week, the report and accounts given in our issue for October 14th were adopted. Mr. Bernard Drake, the chairman of the company, presided. He attributed the unfavourable financial result, compared with the previous year, to stagnation in trade, which has especially interfered with progress in the electrification of mills in Lancashire. Metal filament lamps have also reduced the value of independent contracts, although a large amount of work in lighting small houses was anticipated in consequence of the new lamp.

SWANSEA IMPROVEMENTS & TRAMWAYS CO.—The report for the June half-year shows a profit of £5,289, in addition to £1,561 brought forward. The sum of £1,000 has been placed to depreciation fund, and, after meeting preference dividends, the sum of £4,551 is carried forward.

CLYDE VALLEY ELECTRIC POWER CO.—The accounts for the past half-year show a net profit of £4,084, which is carried forward. The connections now aggregate 27,725 h.p., an increase of 3,344 h.p. during the half-year.

EDISON & SWAN UNITED ELECTRIC LIGHT CO.—The report for the year to June 30th shows a net profit of £421, to which is added £9,606 brought forward. The whole of this is carried forward. The sum of £5,500 has been set aside as depreciation, and £4,000 in writing down stock. The report states that the manufacture of metal filament lamps has been considerably extended during the year, and that the satisfactory results justify the directors in looking forward to a large remunerative trade in the future.

Electric Lighting Acts (Amendment Bill).—Scottish Corporations owning electricity works sent a deputation last week to Mr. A. J. Tennant, the Parliamentary representative of the Board of Trade, in relation to the clause in the Electric Lighting Acts Amendment Bill dealing with supply by unauthorised distributors. The Board of Trade are proposing to add a proviso to this clause to the following effect, viz., that the provisions of the Act "shall not prevent any company who at the passing of this Act are empowered by their memorandum of association to generate electrical energy from affording a supply to a railway company for purposes incidental to that company's undertaking other than the conveyance of public traffic." To this the Scottish authorities took strong exception. The Bill came up for consideration in the House of Lords on Tuesday, and, according to the *Daily Telegraph*, a discussion took place upon this proposal. Lord Belper, who moved the amendment, pointed out that the object was to allow electric supply companies to supply electrical energy to railway companies for the purposes of the company, and not for traction. The amendment was opposed, but it was eventually agreed to. The amendments made in the Bill in the House of Commons were also agreed to.

The New Cross Telephone Exchange.—On October 16th the National Telephone Co. transferred the subscribers connected to its New Cross exchange to a C.B. equipment installed in new premises in Briant Street, which have been specially designed. The new equipment has been manufactured and installed by the Western Electric Co., of North Woolwich, and is of the No. 1 C.B. type, consisting of thirteen subscribers' positions, giving accommodation for 1,500 lines, five in-coming junction positions, one electrophone position, and one exchange-testing position. The ultimate capacity of the exchange is 4,500, and the equipment is of similar design to that installed at the Company's Birmingham-Midland, Altrincham, Hillhead, Bromley, and Dalston exchanges.

Birmingham Section, I.E.E.—The first meeting of the Birmingham Local Section of the Institution of Electrical Engineers will be held at the Birmingham University on Wednesday, November 3rd, at 7.30 p.m., when the Chairman, Mr. R. K. Morcom, will deliver his Inaugural Address. The Annual Dinner of the Section will be held on Friday, November 12th, at 7 p.m., at the Grand Hotel.

Institution of Electrical Engineers.—The opening meeting of the Institution of Electrical Engineers will be held on Thursday, November 11th, at 8 p.m., when the premiums awarded for papers read or published during the session 1908-1909 will be presented, and the President, Dr. Gisbert Kapp, will afterwards deliver his Inaugural Address.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £58 5s. to £58 15s. per ton (last week, £59 5s. to £59 15s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Mr. R. Clements has ceased to act as receiver and manager of Messrs. Marples, Leach & Co., Ltd.

Mr. E. Eaton, electrical engineer, 12 George Street, Lancaster, has been adjudicated bankrupt.

Mr. S. E. Smith, electrical engineer, 271 High Street, Lincoln, has been adjudicated bankrupt. The first meeting of creditors will be held at the Official Receiver's offices, 10 Bank Street, Lincoln, on Nov. 4th, at 11 a.m., and the public examination will take place on the same day at the Sessions House, Lincoln, at 3 p.m.

The first meeting of creditors in the bankruptcy of Eric Eaton, electrical engineer, 12 George Street, Ashton-under-Lyne, will be held on Oct. 30th at the Official Receiver's office, Byron Street, Manchester, at 12 noon, and the public examination will take place on November 18th, at 12 noon, at the Town Hall, Ashton-under-Lyne.

IMPERIAL INTERNATIONAL EXHIBITION AWARDS.—The Cowper-Coles Engineering Co., Ltd., has been awarded by the Juries for the different sections of the Imperial International Exhibition a diploma for grand prize in connection with their metallurgical and electro-chemical exhibits, and a diploma for gold medal for mechanical engineering, also a diploma of honour for applied chemistry.

AGENCY WANTED.—A firm at Zurich are desirous of representing British manufacturers of dynamos and parts. They would also be prepared to buy for their own account. Communications should be addressed to the British Consulate-General, Zurich.

EXTENSION OF PREMISES.—Messrs. George Ellison, of Victoria Works, 17 and 18 Warstone Lane, Birmingham, inform us that they have recently completed extensions to their works, which had become necessary owing to rapidly increasing business.

APPOINTMENTS AND PERSONAL NOTES

M. Dolivo Dobrowolsky has been appointed works manager to the apparatus department of the Allgemeine Elektricitäts-Gesellschaft, Berlin.

Mr. A. H. Shaw, of Ilford, has, owing to pressure of other work, been obliged to relinquish the honorary secretaryship of the Associated Municipal Electrical Engineers of Greater London. These duties will in future be undertaken by Mr. A. C. Cramb, of Croydon.

NEW PUBLICATIONS

"The Patent Road to Fortune," by "A Successful Traveller on it." (London: A. Brown & Sons, Ltd.) 3d.

Proceedings of the American Institute of Electrical Engineers. October, 1909. (New York: The Institute.) $1.

"Rose's Universal Code Economiser." By Sydney Rose. (London: Sidgwick & Jackson.) 10s. 6d.

"Arithmetic and Electrical Measurements." By W. R. P. Nobbs. Thirteenth Edition. (London: T. Murby & Co.). 1s.

The Japan-British Exhibition, 1910.—In connection with the forthcoming Japan-British Exhibition at Shepherd's Bush, we have received a plan of the large machinery hall, which shows that the right wing will be divided into three parts, mechanical, electrical, and gas engineering, respectively. The rear portion will be devoted to railway, marine, transportation, and constructional engineering. A letter from the electrical department, accompanying the plan, calls attention to the fact that a supply of direct, single-phase, and three-phase current will be available for lighting and power in the hall.

International Correspondence Schools.—A special issue of the "I.C.S." Student contains a full report of the celebration and banquet in London on September 18th and 19th, already reported in our columns. We understand that, at the request of a large number of students, arrangements are being made for similar functions in large industrial centres throughout the provinces during the month of February, including Bristol, Birmingham, Glasgow, Leeds, Manchester, Nottingham, and Newcastle-on-Tyne. Promises of speeches from many well-known men have been received.

Obituary.—We regret to announce the death of Mr. F. H. Medhurst, who shot himself at the King's Arms Hotel, Croydon, on Tuesday. Mr. Medhurst will be remembered as a consulting electrical engineer, although within recent years he has been more prominently before the public in political circles. He was a member of the Executive Committee of the Tariff Reform League, and has contested one of the Islington Parliamentary divisions in the Conservative interests. He was recently adopted as the prospective Unionist candidate for Stafford. Mr. Medhurst was a member of the Institution of Electrical Engineers.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Oct. 21st, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

20,394/08. **Emergency or Slipper Brake.** P. McCULLOUGH and J. A. PANTON. This mechanism comprises an air cylinder with two pistons working against springs in opposite directions and applying pressure to the track shoes through a system of levers. A valve with three positions, to apply the wheel brakes, or the track brakes, or to take the brakes off respectively, is described. The metal brake blocks have diagonal grooves and ribs to remove grease and dirt from the rails, or may have pockets with carborundum or corundum refills let into them and fixed by running in molten lead. Five claims, seven figures.

20,468/08. **Time-element Relay.** J. G. STATTER. This specification describes improvements in the "Statter" time-element relay. The box containing the suckers can be fixed in several different positions along the armature bar so as to give a variable leverage, in order to alter the time lag. To correct the temperature error, one or both of the metal suckers is constructed of two discs of metals having different coefficients of expansion as copper and steel. Radial grooves are cut in the discs to allow for expansion. Seven claims, four figures.

24,348/08. **Metal Sheathing of Insulated Wires.** J. J. RAWLINGS, H. W. HANDCOCK, and A. H. DYKES. Hard metal sheathing comprising a metal strip with the two edges overlapped and soldered is liable to buckle. According to this invention, a tinned metal strip is wrapped at least twice round the insulated conductor, so that the finishing edge lies parallel alongside the commencing edge. A set is put in the strip so that the finishing edge does not project above the even surface of the sheathing, and the joint is treated with soft solder. The folded strip is drawn through a heated die, the conductor being drawn in at the same time. The previous tinning of the sheath causes it to become solid and equivalent to a solid drawn sheath. Three claims, six figures.

25,556/08. **Regulation of Power-factor.** BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*). The excitation of a synchronous motor taking a leading current and thus improving the power-factor of an A.-C. system, is automatically regulated by means of a Tirrill regulator having, in place of the usual A.-C. control magnet, a solenoid with two windings supplied from potential transformers across two sides of the line, and one floating series coil supplied from a current transformer. The floating coil is mounted on a rod joining the cores of the two potential windings, and the effect of the arrangement is to hasten or retard the time of the closing of the main control contacts in accordance with fluctuations in the power-factor so as to vary the field excitation of the synchronous motor. Three claims, one figure.

28,522/08. **Recording Instruments.** W. O. SMITH and W. PHILLIPS. In order that temporary fluctuations in current, voltage, or power shall not affect the indicating arm of recording instruments, a dash pot by which a time lag can be introduced must be used. This specification describes a dash pot in which the time lag can be increased to any desired extent, even using comparatively thin oil, which allows the arm to show small variations and to return to zero when the instrument is disconnected. The piston does not fit tight, and short studs are provided on it to keep it from touching the wall of the dash pot. Slots with movable covers are provided to adjust the time lag. Four claims, four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: GILBERT [Feeding mechanism] 27,303/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: COPELAND [Insulators for wires or cables] 23,703/08; STEVENS [Feeder boosters] 26,674/08; BRITISH ALUMINIUM Co. and HORN [Joints in wires and cables] 2,611/09; VERNIER [Jointing conductors] 15,413/09; BOURKE [Line insulators] 18,690/09.

Dynamos, Motors, and Transformers: AKT.-GES. BROWN, ROVERI, ET CIE. [Control of machinery] 21,580/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Control of electrically-driven air-compressors] 21,765/08; ELECTROMOTORS, LTD., and GREENHALGH [Machines] 28,324/08; SIEMENS SCHUCKERTWERKE GES. [A.-C. machines] 9,048/09; KUNKEL [Machines] 19,394/09.

Electric Ignition: TRIER, 7,299/09; ROGERS [Transformers and distributors] 16,943/09.

Incandescent Lamps: McKENNA (*Gluhlampenwerk Anker-Ges.*) [Fixing filaments to leading-in wires] 20,915/08; MARTINI, 21,667/08.

Instruments and Meters: CHETWYND, KELVIN, & JAMES WHITE, LTD., and CLARK [Portable magnetic compass] 21,634/08.

Storage Batteries: STEVENS [Battery charging] 26,674/08.

Switchgear, Fuses, and Fittings: FISHER, COATES, CLOTHIER, and A. PEYROLLE & Co. [Switchgear] 20,590/08; RORKE [Switch] 21,674/08; GARSIDE [Motor-starter] 22,228/08; VON ZWEIGBERGK [Magnetic blow-outs] 25,955/08; SUTER [Lamp-holder] 432/09; LAKE (*Cutler-Hammer Manufacturing Co.*) [Multiple switch starters] 5,909/09; BEAVER, STRATTON, SHAW, and CLAREMONT [Terminals] 10,539/09.

Telephony and Telegraphy: FESSENDEN [Wireless apparatus] 13,865/08; SINCLAIR and AITKEN [Telephony] 20,968/08; SAND [Hygienic telephone transmitter] 16,912/09; SIEMENS & HALSKE AKT.-GES. [Telephone systems] 16,928/09; BOURKE [Line insulators] 18,690/09.

Traction: MORDEY [Switches for surface-contact systems] 21,089/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Signalling systems] 23,727/08; MALLINS [Tramcars] 1,019/08.

Miscellaneous: ELEY and BRADY [Miners' electric safety lamps] 25,366/08; BRAUN [Lightning conductor for airships] 26,567/08; JACKSON and GAFFNEY [Door switches] 27,953/08; OTTO [Electrically heated air-baths] 1,922/09; LAKE (*Hasela Fabrik Patentierter Neuheiten, C. Hubert Schaettgen*) [Electric time alarm] 5,595/09; VANDATTE and LAGYE [Electrical process for removing grease from wool] 5,859/09; SMITH [Fire alarms and indicators] 6,250/09.

The following Specifications are open to Inspection at the Paten Office before Acceptance, but are not yet published for sale.

Arc Lamps: GEBR. SIEMENS & Co. [Electrodes] 21,374/09; HEIMANN and SCHÄFFER [Running arc lamps in series with incandescent lamps] 22,302/09.

Electrometallurgy: GRUNWALD [Furnaces] 14,937/09.

Telephony: SIEMENS & HALSKE AKT.-GES. [Exchanges] 18,456/09.

Patents Revoked

29,058-9/04. **Sparking Plugs.** L. RENAULT. These two and six other patents taken out by Renault during the years 1901-5 have been revoked under Section 27 of the Patents Act, on the ground of inadequate manufacture in this country. The above, the only ones of an electrical nature, refer to terminals for attaching leads to sparking plugs, and to a special construction of sparking plug, respectively.

2,122/08. **Insulating Material.** W. CLAYPOOLE. This patent has been revoked under Section 26 of the Patents Act, by which revocation can be obtained if the grant was not justified, and no opposition was entered. Notice of the application for revocation was given in ELECTRICAL ENGINEERING, August 19th, 1909, p. 750, and an announcement of the surrender of the patent will be found in ELECTRICAL ENGINEERING, September 23rd, 1909, p. 854.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: J. BROCKIE [Ratchet regulating mechanism] 13,681/05; F. HARRISON [Mercury vapour lamps] 14,033/05.

Dynamos, &c.: OTIS ELEVATOR Co. (*Otis Elevator Co., U.S.A.*) [Control of lift-motors] 14,862/02.

Electric Ignition: J. C. ANDERSON [Sparking plugs] 15,120/05.

Electrometallurgy and Electrochemistry: J. RASCHEN and UNITED ALKALI Co. [Electrolytic cells] 13,662/01; C. A. KELLER [Ferro-silicon alloys] 24,235/01; A. G. BLOXAM (*Columbus Elektricitats Ges.*) [Electrodeposition of zinc] 15,128/02.

Heating: ELECTRIC & ORDNANCE ACCESSORIES Co., R. HANCOCK, and R. F. HALL [Air heater] 14,079/05.

Instruments and Meters: G. HARRISON (*Electric Railway Improvement Co., U.S.A.*) [Recording instruments with spark-perforation] 13,953/05, and [Testing apparatus] 13,954/05; E. J. PIPER [Electrolytic meter] 14,050/05.

Switchgear, &c.: C. C. GARRARD and FERRANTI, LTD. [Overload and reverse current relays] 15,289/04; J. W. BROOKS and A. E. READ [Junction boxes, &c.] 13,918/05.

Telephony and Telegraphy: D. HIGHAM [Telephone repeater] 13,739/01; G. M. HARDINGHAM (*Felten & Guilleaume Carlswerk Akt.-Ges.*) [Air-insulated cables] 13,986/01; I. B. BIRNBAUM (*Telephon-Fabrik Akt.-Ges. vorn J. Berliner*) [Telephone systems] 15,049/02; MARCONI'S WIRELESS TELEGRAPH Co., S. W. ASHLEY and K. A. HINDE [Induction coils] 15,199/03; C. V. BOYS [Wireless telegraphy] 13,828/05.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** *weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

A SUPPLEMENT on Electrical Engineering in Mines (the first issue of a supplement which will be published on the first Thursday of every month) is included in this issue. It opens with a review of the question of inspection and responsibility in connection with electrical work in mines. A useful article on "Cables in Coal Mines," by H. J. Fisher, follows; this deals in a thoroughly practical manner with the author's experiences in the selection and laying of cables, and the faults that are likely to arise through proper methods and precautions being neglected. A description is given of a fine example of large main-shaft electrical winding plant on the Ilgner system with flywheel motor-generator, from a recent Paper by Mr. W. H. Patchell. It is illustrated with good photographs of the actual machines, and contains a mass of technical data. The names of the Committee appointed to revise the Special Rules are given, and an account of the recent proceedings of the Institution of Mining Electrical Engineers. Other articles relate to telephones for mines, automatic high-tension oil switches, miners' electric safety lamps, and switchgear for coal-cutters.

MR. C. A. ABLETT read a Paper recently before the Institution of Engineers and Shipbuilders in Scotland on electrically-driven reversing rolling mills. He described the working of the Ilgner system with flywheel converter, and gave some particulars of the latest forms of rolling-mill motors with forced ventilation. He explained also the control and safety devices employed. It was mentioned that the flywheel sets could be driven direct by steam turbines, and the use of exhaust-steam turbines for such work was suggested. (Page 945.)

THE summonses against the Welsbach Incandescent Gas Light Co., Ltd., for applying a false trade description to their metal filament lamps, were again considered by Mr. Bros at the Clerkenwell Police Court on Saturday. Evidence with regard to the purchase of lamps was heard, and the case was again adjourned. (Page 946.)

A PAPER on superheated steam by Mr. A. B. Mountain (Borough Electrical Engineer, Huddersfield), dealing both with its advantages and limitations, was discussed last week at an informal meeting of the mem-

Digitized by Google

bers of the Leeds Local Section of the Institution of Electrical Engineers. (Page 947.)

Some particulars of the turbo-generators of the Lahmeyer Electrical Co., which are combined with Zoelly turbines by Messrs. Escher Wyss & Cie., are given on page 947.

The Postmaster-General's annual report contains some interesting figures relating to the growth of the telegraph and telephone service in this country. The number of telegrams has decreased by 1·3 per cent, but the telephone system is steadily growing. Although the revenue from the telephone system showed a large increase, there was a working deficit in this department of over £45,000. A number of new licences for wireless stations have been granted, and the business in radio-telegrams is increasing. (Page 948.)

The new generating station of the Stepney Borough Council was formally opened by the Mayor on Wednesday last week. (Page 948.)

Messrs. Siemens Bros. Dynamo Works, Ltd., have opened new show-rooms in Upper Thames Street. (Page 948.)

The inaugural address of Mr. W. M. Rogerson as chairman of the Leeds Section of the Institution of Electrical Engineers contained a review of some of the principal changes which had taken place in regard to electric supply and tramway work during the last few years. (Page 949.)

Among the specifications published by the Patent Office on Thursday last was one by the Glühlampenwerk Anker-Ges. for a method of attaching metal filaments to the leading-in wires, consisting in depositing a metal coating on the end of the filament before fusing it to the wire. Apparatus for registering telephone calls and delivering a check to the subscriber for each successful call is protected by D. Sinclair and W. Aitken. Mr. Mordey has taken out a patent for his method of arresting or preventing the arcs formed at the switches of surface-contact traction systems. The Akt.-Ges. Brown, Boveri & Cie., describe a flywheel load-equalising set for A.-C. systems, in which the flywheel machine is automatically controlled by means of an auxiliary commutator motor connected in cascade; and W. Copeland protects a line insulator, in which the wire is secured by means of a metal cap. Three patents have been granted in spite of opposition. One of these is by T. Wardell for a magneto-generator, and the other two are by Siemens & Halske Akt.-Ges. for processes of manufacturing metal filaments. Among the patents expiring this week is one by J. O. Elmore for apparatus for effecting rapid electrolytic deposition of metals; another by E. J. Mercadier and H. R. Pierquin covers a relay and other apparatus for use in multiple telephony and telegraphy. (Page 950.)

We give some particulars of the constructional details of the A.E.G. steam turbines. Very low steam consumptions have been obtained with these turbines, which are of the impulse type. (Page 951.)

A special form of lamp-holder for radiator lamps is described on page 951.

A case was commenced in the King's Bench Division on Tuesday, in which S. M. Bodie was sued for the return of £1,000 paid to him as premium by a pupil named Irving. The latter alleges that all Bodie's stage performances of hypnotism and cures by the aid of electricity are fraudulent, and that he had a staff going around the country with him who posed as members of the audience. Evidence was given by one of these hired men to this effect. (Page 953.)

Two schemes for the construction of tube railways in Buenos Ayres have been sanctioned.—A restricted-hour system of charging is under consideration in Sydney.—The powers of the Somerset & District Electric Power Co. in Bath have been annulled.—A resolution in favour of tramways through the City of London has been passed by a tradesmen's association.—Leeds Corporation are asking the Board of Trade to licence the use of trolley omnibuses.—The Board of Trade have refused to permit trailer cars to be used on the Swansea tramway system.—A question of damages for non-completion of contract in the specified time has arisen between the Wimbledon Council and Messrs. J. Howden & Co.—A scheme of conciliation boards for the L.C.C. tramway employees has been prepared. (Page 953.)

Cleethorpes Council propose to borrow £4,000 for electrical purposes; Dundalk Council, £20,000; and Middleton Council, £3,000. Electrical stores are required by Dublin United Tramways Co. and Messrs. Cadbury. Extensions are contemplated at Oldham. Several large tramway extensions are recommended by the Highways Committee of the L.C.C. (Page 954.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, NOVEMBER 4th.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster, London. Paper to be read:—"Technical Popular Fallacies," by A. S. E. Ackermann.

Rontgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London. Mr C. E. S. Phillips will deliver his Presidential Address.

TUESDAY, NOVEMBER 9th.

National Electrical Manufacturers' Association.

2.30 p.m. Committee meeting at Balfour House, Finsbury Pavement, London, E.C.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Supper and Smoking Concert at the Morley Hotel, Manchester.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. Papers to be read:—(1) "The Single-phase Electrification of the Heysham, Morecambe, and Lancaster Branch of the Midland Railway," by J. Dalziel and J. Sayers; (2) "The Equipment and Working Results of the Mersey Railway under Steam and under Electric Traction," by J. Shaw; (3) "The Effect of Electrical Operation on the Permanent Way Maintenance of Railways as Illustrated on the Tynemouth Branches of the North-Eastern Railway," by C. A. Harrison.

THURSDAY, NOVEMBER 11th.

Institution of Electrical Engineers.

8 p.m. Open Meeting of the Session, when the premiums for the past session will be presented. The President, Dr. Gisbert Kapp, will deliver his Presidential Address. A marble bust of the late Dr. John Hopkinson will be presented to the Institution by Professor Bertram Hopkinson, on behalf of his mother, Mrs. John Hopkinson.

Institution of Electrical Engineers: Dublin Section.

8 p.m. Opening Meeting of the Session at the Royal College of Science, when the Chairman's Address will be delivered.

FRIDAY, NOVEMBER 12th.

Institution of Electrical Engineers: Birmingham Section.

7 for 7.15 p.m. Annual Dinner at the Grand Hotel, Colmore Row.

Physical Society.

8 p.m. Meeting at the Imperial College of Science, London. Among the Papers down for reading is "Some Further Notes on the Physiological Principles Underlying the Flicker Photometer," by J. S. Dow.

Telegraph Traffic.—On the 28th ult., the El Arich route was interrupted between Beyrouth and Jaffa, but was restored on the 30th ult.—On the 28th the Sitka-Valdes cable broke down, but notwithstanding this occurrence telegrams to Glacier, Hadley, Haines Mission, Juneau, Ketchican, Shops, Sitka, Skagway, and Wrangell can be accepted at the normal rates.—On the 30th ult., the cable of the Indo-European Telegraph Co. between Lowestoft and Emden ceased working, but other routes were employed to forward traffic.—Early this week the cable between Balikpapan and Kwandang broke down, and it is necessary to send telegrams for Menado, Kwandang, and Gorontalo, *via* Jap, while those to other places have to be sent *via* Singapore, or the Cocos Islands.—The Tourane-Amoy, Assab-Perim, Dakar-Conakry, Cheikh Said-Perim, Tangier-Mogador, and Paramaribo-Cayenne cables are still on the sick list. The Perim cables have been interrupted since July.

ELECTRICALLY DRIVEN REVERSING ROLLING-MILLS

A PAPER on the above subject was read by Mr. C. A. Ablett, of Messrs. Siemens Brothers Dynamo Works, Ltd., last week before the Institution of Engineers and Shipbuilders in Scotland. The author commenced by describing the Ilgner system which is usually adopted. In the accompanying figure, *A* represents the mill motor, which is a direct-current shunt-wound machine; *B* represents the fly-wheel converter set, which consists of the variable-voltage direct-current generators *C*, the fly-wheel *F*, and the motor *D*, which may be a direct-current electric motor, a three-phase electric motor, or a steam turbine, or other prime mover; *G* represents the driver's platform with the necessary control apparatus.

In speaking of the speed control of the mill motor, which is effected entirely by varying the excitation of the fly-wheel generators, it was pointed out how, with a definite position of the controlling lever, a definite speed was imposed upon the mill motor, above which a braking action took place, so that there was no possibility of racing when the ingot left the rolls, as usually happened with a reversing mill engine. Also within such limits the turning-moment is independent of the speed, and thus the motor can give its maximum turning-moment without any appreciable decrease in speed, and so avoids the loss of time which occurs due to the engine slowing

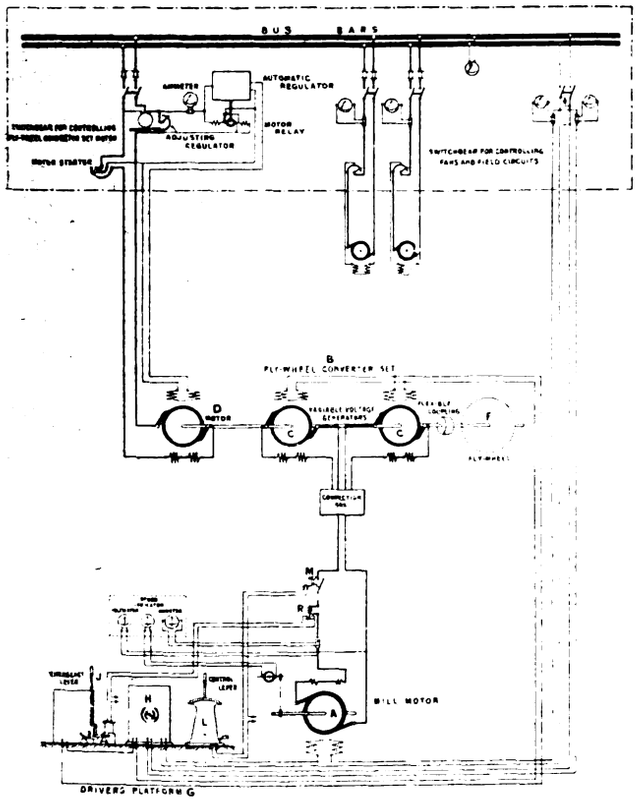

DIAGRAM OF CONNECTIONS.—ILGNER SYSTEM OF ROLLING-MILL DRIVING.

up. The turning-moment given by a reversing mill motor is the same whatever the position of the armature, so that such a motor can give its maximum turning-moment in any position, and there is no chance of stalling, due to points of minimum turning-moment.

The fly-wheel converter set is usually permitted a maximum fall in speed of 20 per cent., and this allows 36 per cent. of the total stored energy of the fly-wheel, which it has when running at full speed, to be utilised for neutralising the fluctuations of power. It often happens that the fly-wheel during the later passes has to give out more energy during the pass than it can regain during the interval between the passes; but during the earlier passes the fly-wheel receives more energy in the interval than it is required to give out during the passes. This increased amount of energy which the fly-wheel receives during the earlier passes has to be arranged to balance up the amount of energy which it cannot regain during the later passes. The fly-wheel, therefore, performs two functions: it stores up energy during the interval between passes and gives out energy during the passes themselves, and, on the whole, it also gains energy during the period of the earlier passes and loses energy during the period of the later passes. When one ingot is following another rapidly, the fly-wheel starts somewhere about its lowest speed with a new ingot, and gains speed until it is at about its top speed, when the ingot is about half rolled down, and has come down to the lowest speed again at the last pass. Superimposed upon this variation of speed are the smaller variations corresponding to the energy which the fly-wheel gains during the intervals between passes, and loses during the passes themselves. A relay is placed in the main circuit supplying the fly-wheel converter set, which causes the latter to fall in speed automatically when the fly-wheel is called upon to give up its stored energy. When the source of supply is direct current, the motor is shunt-wound, and a system of relays actuates a rheostat in the field circuit of the motor and decreases its speed. When a three-phase supply is being used, a similarly arranged regulator inserts resistance into the rotor circuit of the fly-wheel induction motor to increase the slip.

As the mill motor has to reverse frequently, its average speed is considerably less than the maximum, and its heat constants are not so good as if it ran continuously at its full speed, and from the point of view of heating, the armature should be very amply dimensioned so as to provide sufficient cooling surface. On the other hand, however, as the motor has to reverse frequently, perhaps ten or more times a minute, under working conditions, the amount of stored energy which has to be taken from the armature and returned to it again at each reversal should be kept as small as possible, and so to meet with this condition the dimensions of the armature should be kept small. The difficulty caused by these two conflicting requirements is overcome either by providing a mill motor with two armatures instead of one, or by providing forced draught for cooling the mill motor. When the mill motor is provided with two armatures they can be built with suitable electrical proportions, but with a much less radius of gyration than a single armature would have, and so the kinetic energy stored up in the armature when running at full speed, and which has to be given up and replaced again at each reversal, would be considerably diminished, while the cooling surface would be greater. When forced draught is provided, the rate of cooling of the armature is very much increased, enabling the first-mentioned difficulty to be overcome, and a single armature motor with an armature of moderate dimensions can be provided which has a reasonably small amount of stored energy when running at full speed.

The motor is built of the totally enclosed type in order to direct the current of cooling air to those surfaces near which heat is generated, and where the cooling air can give the most beneficial effect, and in order to provide the same amount of cooling air, whether the motor is standing or running, and to keep the rate of cooling constantly at its maximum value, the cooling air is supplied from a motor-driven fan, and not from fans fixed to the armature. A second motor-driven fan is always kept in reserve, in case of accident to the first. It is very necessary that reasonably clean air should be provided for the forced draught for the motor, for the lodgment of damp or dirt in the motor would cause serious trouble. Such difficulties are much more likely to occur with forced draught than when a motor is running unenclosed in a damp or dirty atmosphere, because much more air comes in contact with the working parts of the motor in a given time, and the air is being directed on to the working parts with considerable velocity. It is, therefore, found necessary that the fans which supply the forced draught should draw their air in through a filter. Such a filter is of very simple construction, consisting of a wooden box in which a piece of cloth is stretched, through which the air is drawn, the cloth often being arranged in zig-zag fashion to get as much surface as possible. A 2,500 h.p. mill motor provided with forced draught cooling would require about 500 cubic ft. of air per minute, at a pressure of about 2¼ oz. per sq. in.

It is found best to run the fly-wheel converter set at a speed of 400 or 500 revolutions per minute, according to the power required, in order to obtain the most advantageous arrangement with regard to dimensions and capital cost. This speed enables a normal motor, running at its natural speed, to be employed as the driving motor, and a fly-wheel to be used of the maximum dimensions that can be carried on the railway, and which runs near the maximum peripheral speed allowed by good practice, being as light as possible in proportion to its stored energy. Two or more variable voltage generators are employed because these machines have to deal with the very large powers required by the mill motor; for if only one variable voltage generator were provided, the

Digitized by Google

armature and commutator would have to be of such diameter, in order to secure favourable electrical conditions, that the peripheral speed would be too high to secure satisfactory operation, but when several machines are employed they can be of normal design in every respect. As the fly-wheel would weigh from ten to sixty tons or so, according to the conditions of working of the mill which the fly-wheel converter set serves, it is carried in separate bearings, and though these bearings are usually provided with forced lubrication, they may wear down somewhat faster than those which support the comparatively light electrical machines. In the case of a single fly-wheel converter set used for two separate reversing mill motors, separate variable voltage generators are used for each mill motor, so that each mill may be controlled independently of the other. The fly-wheel in this case would be lighter than would be required if one mill only was driven, as the probability is in favour of the passes in each mill not occurring at the same instant. Another arrangement is to provide two separate fly-wheel converter sets for driving two mills. One of the variable voltage generators on one fly-wheel converter set would be put in series with one of the generators in the other set for driving each mill, and so both fly-wheels become available for neutralising the variations in power required by each mill. When it is only desired to run one mill the connections can be changed so that one fly-wheel converter set only is used.

As previously mentioned, the speed of the mill motor is controlled by means of a rheostat in the field circuit of the variable voltage generators, which alters the resistance of the field circuits, and hence the field currents. This rheostat, marked *H* in the diagram, is actuated by means of the control lever *G*, which is under the control of the driver, and which works backwards and forwards in a straight-line motion in a plain, straight slot in the quadrant of the control frame, in a somewhat similar manner to the reversing gear of some locomotives. The resistance is so arranged that the speed of the mill is proportional to the angular displacement of the lever of the central position.

The following safety devices are employed :—

1. An emergency controller is provided which is actuated automatically by a weight which can be set into motion by suitable trip gear. This controller serves to increase the resistance in the field circuit of the variable voltage generators step by step, and finally to open the field circuit of these generators, thereby bringing their voltage to zero and bringing the mill motor to a standstill.

2. An automatic maximum current cut-out is provided in the circuit between the variable voltage generators and the mill motor, which serves to interrupt this circuit. While the main control lever, *L*, is placed on the right hand side of the driver, the emergency lever *J* is placed on the left hand side, and in case of any accident occurring, all the driver has to do is to pull over the latter lever. This first trips the weight, setting the emergency controller into operation, reducing the voltage supplied by the variable voltage generators to zero, and finally trips the automatic maximum current cut-out, thereby opening the main circuit to the mill motor. A current relay is also provided in the main circuit, which, when the current has reached a predetermined value, first trips the weight, setting the emergency controller into operation, and then opens the maximum cut-out. These arrangements provide against the variable voltage generators being seriously overloaded, or against undue strains being put on the mechanical parts of the mill, for instance, when too great a draught is taken on an ingot, or when the driver tries to roll down a cold ingot with too heavy draughts. They also serve to protect the mill motor or the variable voltage generators from possible damage owing to short circuits.

3. As the conditions of commutation do not permit the mill motor to take so much current when it is speeded up by weakening its field, the above-mentioned automatic devices would not operate before such a current had been obtained which might cause unsatisfactory commutation, and so the driver is provided with an additional lever, to short circuit the resistance in the mill motor field, should the mill motor take excessive current when it is running at a high speed. This would reduce the speed of the mill motor to a point at which it could safely take this current.

4. In order to provide against the process of rolling being carried out so fast that the fly-wheel converter set had not time to recover its speed in the intervals, and the speed falling below the permissible limit, a tachometer is provided for the fly-wheel converter set, so arranged that when the pointer falls below the lowest permissible speed it closes a circuit, and lights a lamp on the driver's platform warning him to go very easily. An arrangement can also be fitted so that when this lamp lights, a small magnet interposes a stop in the way of the control lever, so that the mill motor can only be run at a moderate speed, and the work carried out slowly until the fly-wheel converter set has regained its speed.

An ammeter which shows the current which the mill motor is using and a tachometer which shows the speed of the mill motor are mounted in front of the driver, so that he can easily see them without interfering with his view of the mill. This tachometer is really a voltmeter supplied by a small magneto machine which is connected to the mill motor shaft, and is so graduated that its readings indicate the speed at which the mill motor is running.

It has been found practicable to run fly-wheel sets direct from a steam turbine at moderate speed, and Mr. Ablett suggested that a considerable field was opened up by the possibility of thus working a reversing mill by the exhaust steam from an old steam mill.

THE WELSBACH METAL FILAMENT LAMP: ACTION BY GENERAL ELECTRIC CO.

IN the Clerkenwell Police Court on Saturday, Mr. Bros again sat to hear the summonses taken out by the Wolfram (Tungsten) Metal Filament Lamps, Ltd., and the General Electric Co., Ltd., against the Welsbach Incandescent Gas Light Co., Ltd., for applying a false trade description to the metal filament lamps which they have recently put upon the market. Mr. Rufus Isaacs, K.C., M.P., Mr. H. A. Colefax, and Mr. E. Lunge are appearing for the prosecutors, and Mr. A. J. Walter, K.C., and Mr. A. H. Bodkin for the Welsbach Co. The hearing only lasted one and a half hours, and owing to the delay through the magistrate's clerk, as is the custom, taking down the evidence in longhand, the testimony of only one witness was completed.

Mr. F. H. Hale, who described himself as an assistant manager in the Despatch Department of the Lamp Department of the General Electric Co., stated that on September 29th, under instructions from Mr. J. Y. Fletcher, the manager of the Electric Lamp Department, he went to the Welsbach Company's premises in Gray's Inn Road and purchased two lamps, being assured, both in the showroom and the warehouse, that the lamps were Baron Von Welsbach's. On October 8th he received further instructions from Mr. Fletcher, and made a purchase of eighteen 25-c.p. 100-volt lamps. On this occasion he asked the salesman to state on the invoice that the lamps were Baron Von Welsbach's, as his customer made a special point of this. The salesman replied "Certainly," and a statement to this effect was put upon the invoice. He was not aware that the Welsbach Co. made metal filament lamps, but he always regarded the Auer Gesellschaft, of Berlin, as the chief makers of this class of lamp. This company was known in London as the Auer Co.

In cross-examination by Mr. Walter, witness stated that when he made the purchases of lamps referred to, he presented a trade card in the name of Holloway, Bath Road, Hounslow. This card was given him by Mr. Fletcher, but he had no knowledge of the existence of such a person. He was not aware that the card was printed specially for this purpose. During his cross-examination, Mr. Walter put it to the witness that the two salesmen of the Welsbach Co., with whom he dealt, denied that he made any request for the statement that the lamps were Baron Von Welsbach's to be placed upon the invoice. They alleged that the witness asked them to put it on if they had no objection. Mr. Walter also produced an "information" signed by the witness with regard to these purchases, in which he said nothing about having asked for a statement that the lamps were Baron Von Welsbach's to be placed upon the invoice of October 8th.

In reply to questions as to where he had seen the Auer Gesellschaft referred to as the Auer Co. in London, witness said he had seen the correspondence between that company and the General Electric Co., but had not seen the name in any other connection. He did not know that the Auer Gesellschaft was under contract not to use the words "Auer" and "Welsbach" in the United Kingdom. Neither was he aware that the word "Aur," which was the registered trade-mark of the Welsbach Co., had hitherto been placed upon all the goods which they sold.

The hearing was again adjourned until Saturday.

Electric Power in the American Textile Industry.—The use of electric power for driving textile machinery in the New England States is steadily increasing. There are now some forty steam turbine generating plants in this important manufacturing district. Of these sixteen—with a total capacity of 49,500 h.p.—were installed by the General Electric Co. (U.S.A.), thirteen (15,000 h.p.) by the Westinghouse Electric and Manufacturing Co., and eleven (23,500 h.p.) by the Allis Chalmers Co. Besides these steam plants, there are a number of water-power stations, which supply motors driving textile machinery to the amount of some 175,000 h.p.

SUPERHEATED STEAM

AN informal Paper by Mr. A. B. Mountain (Borough Electrical Engineer, Huddersfield), on superheated steam, was discussed at a meeting last Tuesday of the members of the Leeds Local Section of the Institution of Electrical Engineers. After referring briefly to the usual methods of adding heat to the steam generated in the boiler, he remarked that considerable discussion had taken place, and many forms of superheater had been designed to enable the degree of superheat to be varied or maintained at one constant temperature. Most of these introduced undesirable complications, but without a system of bye-passing a part of the saturated steam to mix with the superheated steam, there was undoubtedly a risk of getting steam at a much higher temperature than was desirable when fires were being forced, or when a large load was taken off, leaving only a small quantity of steam to pass through the superheater. The extent to which the temperature may be raised in practice is limited by the flash-point of the cylinder oil in reciprocating engines, and by considerations of rotor expansion and clearances in the case of steam turbines.

Mr. Mountain showed a table of figures giving test results to demonstrate the saving in steam consumption, due to superheating, for both turbines and reciprocating engines. Apart from the increased efficiency of the engine, there was considerable saving in the steam pipes, as is shown by the smaller amount of water coming from the steam traps. Against these savings must be put increased cost of repairs, oil and attention, which might even outweigh the gain unless the engines are specially designed for superheat. In his own case, with steam at 460 to 520° F., he had to reconstruct some of the engines, due to valves and pistons seizing. Where slide valves were used they had to be carefully balanced to reduce the friction on the rubbing faces to a minimum. Piston rings and H.P. packings must also have very light pressure. Another trouble is the distortion of cast-iron valve seatings. In this connection Mr. Mountain was able to bear out Professors Rugan and Carpenter's observations on the "growth" of cast-iron after repeated heating. This trouble is avoided by the use of cast steel bodies.

Lubricating oil must be very carefully selected, and in his experience gravity feed lubricators were not sufficiently reliable with superheated steam. He had adopted mechanically-operated lubricators with more satisfactory results. He suggested that where reciprocating engines alone were employed, only sufficient superheat be given to enable dry steam to be delivered to the engine; this would then depend upon the length of steam pipe between the boiler and engine.

Mr. McLAREN (Leeds) opened the discussion, and said that superheaters had been the salvation of water-tube boilers, and had done much to bring turbines to their present high efficiency. The system was only possible with solid-drawn steel tubes, as they sometimes get red-hot. It was not, in his opinion, the right place to fix the superheater direct at the back of a dry-back boiler, although such practice might give satisfactory results in the case of Lancashire boilers. He advocated the use of balanced slide valves of special construction in preference to piston valves, the latter being liable to seize when hot.

Mr. HARRIS (Messrs. McPhail & Simpson, Ltd., Wakefield) advocated mixing saturated steam with the superheated steam to avoid excessive temperature in the engine. It was unwise to fix the superheater directly opposite the flues in a dry-back boiler; his firm divided it and fitted the tubes on each side of the chamber.

Mr. HOLMES (Messrs. Pollit & Wigzell, Sowerby Bridge) emphasised the importance, with Corliss and drop valves, of seeing that the valve seat was properly fixed, or otherwise it might come loose. The advantages of superheat were more pronounced with low pressures.

Mr. KILBURN (Messrs. Hopkinsons, Ltd., Huddersfield) referred to numerous experiments they had made to study the effect of great variations of temperature on cast-iron, and passed round a sample plate, showing the enormous growth attained. The greater the variation of heat to which the iron is subjected the greater the effect on the iron.

Mr. WILSON HARTNELL (Leeds) pointed out that the quality of the cast-iron used in the engines made a great difference when high temperatures were experienced. A well-known firm had at first used iron containing a large proportion of phosphorus, but they now found it better to use a graphitic iron for withstanding high temperatures.

Mr. A. McLAREN (Leeds) observed that many slow-speed Corliss engines were running very well with superheat without any modifications. The time to look for trouble was when high superheat is used with high-speed engines.

Mr. THURSFIELD considered the chief advantage in the use of superheat consisted in raising the efficiency of the steam pipes and auxiliaries. In his opinion, heaters fired by the boilers were better than separately fired superheaters. He also preferred regulation to be effected by deflecting the heat, rather than by by-passing the steam.

Mr. R. H. CAMPION (Borough Electrical Engineer, Dewsbury) had fixed superheaters to two of the five boilers, and this enabled him to keep one boiler always in reserve. He used Willans' engines, and by making up with saturated steam he was able to keep the engines in constant use without any trouble. He suggested that much of the trouble experienced by Mr. Mountain was caused by using too high a temperature.

Mr. R. S. GALLAHER (Manchester) said that superheat reduced the loss due to radiation owing to the lack of moisture in the pipes. The secret of slide valves working satisfactorily at 500° is found in perfect lubrication.

Mr. H. DICKINSON (City Electrical Engineer, Leeds) has experienced no trouble with the form of valve advocated by Mr. McLaren, although he was working with 460° on the engine stop valve. He found it best to use a good oil and lubricate in the right positions. With more jets fixed in the proper places the oil consumption was actually reduced to a quarter, and with better results.

The Chairman, Mr. W. M. ROGERSON (Borough Electrical Engineer, Halifax), mentioned he had superheated for five years. The temperature at the superheater itself varied from 550° to 570°, and on the water-tube boilers from 400° to 450°. He had no trouble in working with a temperature of 500° at the stop valves. The mistake was in trying to use too high a temperature.

LAHMEYER TURBO-GENERATORS

WE have received from the Lahmeyer Electrical Co., Ltd. (Bank Buildings, 109 New Oxford Street, London, W.C.), some particulars of the turbo-generators supplied by that firm. The stators of the alternators are built up with a large number of ventilating ducts, and air is drawn in through filters at both ends of the generator frame by a ring of vanes on each end of the rotor, and expelled in a downward direction through a special opening in the middle of the frame. The stator winding consists of flexible cable in semi-enclosed slots insulated with micanite; low tension generators are bar wound, and insulated with leatheroid, presspahn, and impregnated tape. The rotor is of steel, and the flat strip windings, covered with leatheroid, are embedded in slots milled out of the solid forged core in the sides of the polar projections or in the periphery. The ventilating ducts in the pole faces are connected by axial tunnels. Brass end-plates and covers hold in the end connections of the rotor. The brass slip-rings are mounted on steel bushes. Leaf metal brushes of the Endruweit pattern are employed. In single-phase alternators the rotor is built up of thin stampings and has brass supports for the windings. These supports serve at the same time as short-circuiting rings for a bar winding imbedded in the pole shoes to reduce eddy currents in the shoes and to damp the hunting action of the rotor.

The continuous-current turbo-generators of the Lahmeyer Electrical Co. are all interpole machines, with a compensating winding in the main pole faces, only when the commutating conditions are very exceptional. These machines are enclosed and ventilated in a similar way to the three-phase machines.

Messrs. Escher, Wyss & Cie., of Zürich, the original manufacturers of the Zoelly steam turbine, are now affiliated with the Lahmeyer Electrical Co., and the latter firm have already supplied a large number of turbo-generators coupled to Zoelly turbines. Among these are a 5,700 k.v.a. 3,200 v., 1,000 r.p.m. three-phase set for the Charlottenburg Municipal Electricity Works, a 1,875 k.v.a. 5,250 v., 1,500 r.p.m., three-phase set for the Municipal Electricity Works at Warsaw, and a 1,875 k.v.a., 10,500 v., 1,500 r.p.m. set for the Gummersbach Electricity Works, Germany.

Students' Section, I.E.E.—The following arrangements have been made in connection with the meetings of the Students' Section of the Institution of Electrical Engineers. The meetings will be held in the Library of the Institution, 92 Victoria Street, Westminster, London, on alternate Wednesday evenings, commencing at 7.45 p.m., and the programme for next session is as follows:—November 17th, Opening Address by Mr. J. H. Rider, on "The Importance of Attention to Details"; December 1st, "Special Rheostats," by Jeffrey S. Messent; December 15th, "Electricity Supply on Tap," by C. B. Nadaud and W. Bernard Thompson; January 19th, "Collection of Current at High Peripheral Speeds," by P. J. Cottle and J. A. Rutherford; February 2nd, "Direct-current Railway Motors for High Voltages," by Ernest V. Pannell; February 16th, "Alternating *versus* Direct-current Supply," by H. W. Gregory; March 2nd, "Insulating Materials," by Thomas J. Sack; March 16th, "Wireless Telegraphy," by M. Barrington-Baker; April 13th, "The Theory and Design of Current Transformers," by Arthur P. Young; April 27th, "Some Notes on Current Central Station Design in Germany," by John C. Conman; May 4th, Annual General Meeting. The following Paper will also be read:—"Private Electricity Supply and Distribution," by R. C. Plowman. No programme of visits to works has been arranged, but suggestions are invited, and should be sent to the Hon. Sec., Mr. G. H. Stevens, 9 Yerbury Road, Tufnell Park, London, N.

THE POSTMASTER-GENERAL'S ANNUAL REPORT

THE fifty-fifth annual report of the Postmaster-General deals with work of the Post Office for the year ending March 31st, 1909. The number of telegrams transmitted over the Post Office wires during the year was 84,825,000, a decrease of 1·3 per cent as compared with the previous year, due to the increasing use of the telephone, especially for local communication. The telegraph system has been extended by 215 post offices, and there are now 11,077 offices in the United Kingdom, excluding 2,413 at railway stations and other public places. The metropolitan intercommunication switch system has effected a further increase in the speed of transmission of telegrams in London. Experiments are being made with various patterns of keyboard perforators and transmitters, and the Pollak-Virag system, but no results are given in the report. Several underground telegraph lines have been extended during the year, and other pipe lines are in progress of construction, the intention being to provide underground connections with the landing places of the principal submarine cables from the Continent. The number of foreign telegrams dealt with was 9,420,000, an increase of 275,000 as compared with the previous year. During the year practical trials of fast-speed apparatus have been made on some of the Anglo-Continental wires, but the results have hardly been so satisfactory as was hoped. Another kind of apparatus, which seems to promise better results, is about to be tried.

Under the heading of "Wireless Telegraphy," the report, which was written before the recent agreement with regard to the Marconi Co.'s coast stations was completed, states that 28 further licences (covering 48 installations) were granted for stations in the United Kingdom. The whole of these were for experimental purposes. The licences for land stations now in existence include 8 commercial, covering 25 stations; 5 private business (including lightships), covering 11 stations; 105 experimental, covering 164 stations; and 83 minor cases (experimental), in which permission has been given by letter. Up to March 31st last, 15 licences had been granted to shipowners, covering 72 ships. The total number of British ships of the mercantile marine now equipped is more than 100. The great majority of these are Atlantic liners. The report states that the International Radiotelegraphic Convention has worked smoothly and satisfactorily, and its effect on the business of the Marconi Co. is stated to have proved distinctly advantageous. The Post Office has continued to collect and deliver the Marconi Co.'s radiotelegrams to and from ships at sea under the arrangements settled in 1904. The total number of outward radiotelegrams dealt with during the year was 1,817, as compared with 1,725 in 1907–8, and of inward radiotelegrams 22,732, as compared with 20,067. The Post Office station at Bolt Head is working satisfactorily, and is proving of great value in giving the Post Office practical experience of the working of wireless communication with ships, and in assisting towards the administration of the International Convention and Regulations. In addition to the Post Office stations, which now include the coast stations of the Marconi Co., three stations in the United Kingdom are open for public correspondence with ships—namely, a station at Cullercoats, erected by the Amalgamated Radio-Telegraph Co.; a station at Heysham Harbour, erected by the Midland Railway Co. (for communication with their Douglas and Belfast steamers); and a station at Parkeston Quay, erected by the Great Eastern Railway Co. (for communication with their Hook of Holland and Antwerp steamers). The Post Office stations for communications between Tobermory and Loch Boisdale (Marconi system), and between Hunstanton and Skegness (De Forest system), which were erected in 1906, have continued to work satisfactorily. The former pair of stations on one occasion carried as many as 300 telegrams during the day.

Turning to the telephone service, the report states that the number of trunk line exchanges is now 551, 47 new exchanges having been opened during the year. Conversations over trunk lines have increased by 6·86 per cent. During the year 102 ordinary telephone exchanges were opened in the provinces, and 55 public call offices were connected. The extension of the telephone system by adapting existing telegraph wires for local telephone working has been very successful, conversation over such wires having been effected over distances of 50 to 100 miles. The provincial telephone system is growing steadily. In connection with the purchase of the Glasgow system, arrangements have been made for the consolidation of the existing plant and exchanges in that city, and underground wires will gradually be substituted for the present overhead wires. A new central battery exchange is being constructed in Glasgow to accommodate 10,000 lines. The number of Post Office subscribers' telephones in London now stands at 55,125, and new subscribers are being connected at the rate of 140 per week. There are 682 call offices in service, and the calls have increased during the past year by 34 per cent. The amount of royalty received during the year from the National Telephone Co. was £295,828, and from other licencees, £2,618.

The telegraph revenue of the year, including the value of services rendered to other departments, was £3,099,724, a decrease of £1,216: and the telegraph expenditure, including the interest on the capital—£10,867,644—expended on the purchase of the telegraphs, was £4,218,659, an increase of £44,776 upon the previous year. The telephone revenue of the year, including the value of services rendered to other departments, was £1,522,442, an increase of £139,262; and the telephone expenditure was £1,567,570, an increase of £133,219 upon the previous year. The net deficit on working was thus £45,128, or £6,043 less than last year. The net revenue from the postal, telegraph, and telephone services combined was £3,587,364, or £275,199 less than last year.

OPENING OF THE NEW ELECTRICITY WORKS OF THE STEPNEY BOROUGH COUNCIL

THE new electricity works of the Stepney Borough Council, a detailed description of which appeared in our last issue, were opened by the Mayor of Stepney (the Hon. H. L. W. Lawson) on Wednesday last week. Mr. H. H. Gordon, L.C.C., B.A., welcomed the Mayor and Mayoress, and described the nature and extent of the electricity supply in Stepney, quoting figures to show the enormous advance made during the past eight years. In the course of his speech he complimented Mr. W. C. P. Tapper on the able manner in which he had carried on the undertaking. He also referred to an audit which had recently been carried out on behalf of a ratepayers' association which revealed that the business was a very profitable one. The Mayor, in declaring the station open, alluded to the extremely low average charge for electricity supply: the figures for 1909 are, lighting 2·138d. per unit, power and heat 0·945d. per unit, public lighting 1·277d. per unit, and bulk supply 1d. per unit.

After the usual votes of thanks had been passed, the Mayor opened the throttle valve admitting steam to the turbine, and the Mayoress, under the guidance of Mr. Tapper, watched the voltmeter rise to indicate normal pressure, and then switched on the lights in the building with the aid of a silver presentation key.

We regret that in our description of the station last week (page 934) we gave incorrectly the initials of Mr. B. B. Heaviside, under whose superintendence the plant was erected.

MESSRS. SIEMENS' SUPPLIES DEPARTMENT

LAST Monday Messrs. Siemens Bros. Dynamo Works, Ltd., opened new premises at 39 Upper Thames Street, as London stores and showroom, where all the business of the supplies department will be in future conducted, including that hitherto carried on at 6 Bath Street, E.C., and 1 Abchurch Yard, E.C. The new premises, which we were invited to view last week, comprise six floors and a basement, and are arranged in a thoroughly practical manner. The ground floor is fitted for counter trade, and facilities are provided for executing customers' orders promptly. The first floor is devoted to an extensive showroom, one feature of which will be a display of the latest designs in artistic electric light fittings and shades, exhibited in conjunction with the tantalum lamp. The third floor is occupied by the manufactures of Messrs. Siemens Bros. & Co., Ltd., and a comprehensive stock of all sizes of wires and cables is carried. It may be mentioned that "Stannos" wire has been used extensively in wiring the building. The remaining floors contain tantalum and carbon lamps, electric light fittings and shades, conduit and fittings, arc lamps and carbons, meters, small generators and motors, and electrical accessories of all kinds, such as lampholders, switches, fuses, ceiling roses, &c.

The Electric Driving of Printing Presses.—We understand that Messrs. J. H. Holmes & Co. have given notice of appeal against the decision of Mr. Justice Neville in the case in which they sued The Associated Newspapers, Ltd., for alleged infringement of the Clatworthy patent. Mr. Justice Neville considered the patent invalid for the reason that, in his opinion, some descriptions of an American equipment published previous to the application for the patent, included the substance of the first claim, and dismissed the action with costs.

Lamp Traps for Moths.—In order to destroy the moths of the pyralid and cochylis, two larvæ which give much trouble in vineyards, some French experimenters have installed a number of electric lamp traps in a vineyard in the neighbourhood of Rheims. Each trap consists of a 5 c.p. incandescent lamp with an enamelled reflector, from which is suspended, by means of three chains, each 8 in. long, a round tin dish about 15 in. in diameter. The dish contains water with a top layer of petroleum. A number of traps were placed some 75 ft. apart and in rows, and it is said that they were most effective, the moths being attracted by the lamps and killed by the fumes from the oil. The dishes, it is said, should be only a few inches above the ground.

RECENT SUPPLY AND TRAMWAY PROGRESS

MR. W. M. ROGERSON (Chief Electrical Engineer, Leeds Corporation) delivered his inaugural address as chairman of the Leeds Section of the Institution of Electrical Engineers on Wednesday, October 27th, and confined his remarks mainly to a short retrospect of the supply of electrical energy for lighting, power, and tramways.

Ten years ago, he said, 93 Municipalities had established electric generating stations, having a total capital of £5,734,938, while some 70 companies were also undertakers with a total capital of £5,261,763. At the end of 1908 there were 541 undertakings, 338 of which belong to local authorities and 203 to companies or private individuals, the total capital involved being £40,016,300 and £40,722,000 respectively. It will be seen therefore that the capital laid out both by private companies and local authorities has increased in about equal proportion. The total lamps connected, equivalent to 8 c.p., ten years ago, were 4,106,727, which have now increased to 35,056,700, while the output in Board of Trade units sold both by companies and municipalities has increased in ten years from 60,125,500 to no less than 749,594,200.

Taking six typical generating stations, the average cost per unit sold in pence, in 1898, was as follows:—Coal, 0·46; oil waste, wages, repairs, &c., 0·70; works' costs, 1·16; total costs, exclusive of interest and sinking fund, 1·85; while the average costs in the same generating stations to-day are as follows:—Coal, 0·26; oil waste, repairs, &c., 0·30; works' costs, 0·56; total costs, exclusive of interest and sinking fund, 0·78; or roughly, each B.O.T. unit sold in 1898 cost over 1½d. to produce, while to-day the cost has come down to almost ¾d. The most important factor in this reduction of cost had probably been the improvement in power factor due to the increase in power and traction load.

Tracing some of the changes in the details which make up a supply station, he commented on the increased use of water-tube boilers, and the lower and cheaper qualities of bituminous coal that are now being burnt, owing to the great success of mechanical stokers.

The principal changes in the engine house had been the increase in the size and speed of sets, and the introduction of the steam turbine. It was interesting to note that two Parsons' turbines, supplied to the works with which he was connected, ten years ago, when tested gave 28·9 lbs. of steam per kw.-hour at full load, while a modern machine would take about 25 lbs. per kw.-hour under similar conditions, and a large turbine of 6,000 kilowatts capacity might even come down to about 14·5 lbs. of steam per kilowatt under good conditions.

Vast improvements had been made in switchgear to deal with heavy currents and higher voltages. The cost of oil switches and circuit breakers had decreased without the loss of efficiency, and it was noticeable that slate was commonly used now where it was once thought necessary to use marble with insulating bushes. The recent reduction in the cost of aluminium was bringing this material into use in place of copper, now that satisfactory methods of working it had been evolved.

With regard to battery construction, by thorough screening of plates of opposite polarity by porous diaphragms, the tendency to buckling has been lessened, and the avoidance of internal structures as far as possible (plates being now almost universally suspended in tension, instead of resting on bottom blocks) taken together with a liberal clearance for sediment, by putting off the need of cleaning out operations, has tended greatly to increase the useful life of cells. The use of boosters in place of regulating cells had also greatly increased the revenue-earning capacity of batteries. He could foresee a form of remunerative utilisation of electric storage in the supply of current for lighting purposes and power, in districts served by electric tramways, but to which mains had not yet been extended. The employment of a battery, together with a suitable booster and motor generator, would solve the problem of voltage variation satisfactorily. A relatively small battery sufficient to watch over the local circuit, when the breakers come out on traction, and after tramway service hours would suffice.

After a few remarks on mains and meters the chairman passed on to deal with tramway development. In 1898 only some 40 electric tramways were in existence, with a capital of approximately £24,000,000, while from the latest returns there are at present 305 undertakings in the United Kingdom, with a capital of £68,199,918, the gross receipts being £12,439,625, while the total number of passengers carried per annum amount to the large total of 2,625,532,895. The principal improvements which have taken place in tramway apparatus during the last few years, he continued, refer to mechanical detail. Motors instead of having cast-iron fields have the fields now of steel; workmanship has been greatly improved, and motor parts are now made interchangeable. The general tendency has been to protect the armature winding at the ends to a greater extent. Ventilation of the rear and back end of the motor has been largely done away with, as it was found that the disadvantages resulting from the very slight increase of temperature was much more than counterbalanced by the fact that the winding was kept free from dirt. The use of laminated poles in place of cast-iron poles has enabled the pole spacing to be made much more accurately, with consequent improvement of commutation, and with motors of large size, commutating poles are now coming into extensive use; but with smaller motors, where the commutating conditions are naturally good, and where there is little trouble from flash overs, it is questionable whether the addition of commutating poles, with their extra cost and complication, is warranted. Insulation, where possible, is treated before placing into position, and complete armatures are further impregnated in a vacuum. With controllers, the introduction of mica in the construction of the drums to replace sulphur compositions is an advance, as is also the method of providing the fingers with renewable tips, cutting down the cost in this direction very considerably, the number of moving parts in the interlocking mechanism between the main reverse and brake valves has been considerably reduced, thus making the controller simpler and more reliable in its action. Magnetic blow-outs have also been considerably improved, and an interlocking device has been devised, making it impossible to supply power to the motors from the driving end of the car, with the controller on the rear end not being in its correct off position. Thus the up-to-date controller consists of a small number of complete standardised sections, so assisting greatly in its prompt repair, with lessened cost of upkeep.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

DOMESTIC HEATING DEVICES.—Some leaflets are to hand from the Regent Electric Co., Ltd. (52 Regent Street, Piccadilly Circus, London), the manufacturers of the "Holmquist" electric light baths. A new pattern of semi-reclining bath and a folding bath are described, and particulars of electrically-heated hat-pads and bed-warmers are given. The latter comprise resistance wire netting interwoven with asbestos and enclosed in an asbestos cloth cover. Adapters for connecting these appliances to lamp-holders are supplied with them.

STEAM ENGINES.—A new list from Messrs. Alley & MacLellan, Ltd., gives particulars of sizes, outputs, and prices of the latest patterns of this firm's two-crank compound and three-crank triple-expansion high-speed engines. In all except the smallest sizes separate valves are fitted to each cylinder, giving short direct ports and closer adjustment than some designs of central valve engine. Valve liners are fitted on most of the sizes, and this, together with the fact that the ports are cut from the solid casting, conduces to great economy in steam consumption by avoiding the disadvantages of crooked ports, large cylinder clearances, and leakage loss past the H.P. valve.

VARIABLE SPEED INDUCTION MOTORS.—A leaflet from the Maschinenfabrik Oerlikon (34-35 Oswaldestre House, Norfolk Street, Strand) contains particulars of three-phase induction motors, in which as many as five or six economical speeds can be obtained by altering the effective number of poles. Another leaflet with miscellaneous illustrations gives an idea of the large range of the company's manufactures.

REVERSIBLE BOOSTERS.—We have received from the Chloride Electrical Storage Co. (Clifton Junction, near Manchester) an interesting pamphlet describing the "Entz" booster system which, as is well known, depends for its action upon the operation of a pair of variable carbon resistances controlled by a series solenoid. These are connected by a bridge arrangement to the booster exciter field circuit, which they regulate in either direction according to the load. The system is shown to be in extensive use by illustrations of sets at work. By its adoption, complicated adjustments and multiplicity of field-windings on the booster itself are entirely avoided.

Control of Cables in Time of War.—A cable from Melbourne states that the Bill enabling the Commonwealth to seize and control in time of war or emergency the shore ends of ocean cables touching Australia has passed both Houses of the Federal Parliament.

Royal Institution.—The 84th Christmas course of Juvenile Lectures, founded at the Royal Institution in 1826 by Michael Faraday, will be delivered this year by Mr. William Duddell, F.R.S., his subject being "Modern Electricity." The course, which will be experimentally illustrated, commences on Tuesday, December 28th, at 3 o'clock, and will be continued on December 30th, 1909, January 1st, 4th, 6th, and 8th, 1910.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Oct. 28th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.
Names in italics indicate communicators of inventions from abroad.

20,590/08 and 25,366/08. **Mining Switchgear and Electric Safety Lamps.** These two patents are abstracted in the Mining Supplement accompanying this issue.

20,915/08. **Metal Filaments.** T. McKenna. (*Glühlampenwerk Anker-Ges.*) A coating of the metal of which the leading-in or supporting wire consists, is electrolytically deposited on the end of the filament. Fusion of the filaments to the wires is then effected in a blow-pipe flame without oxidation of the filaments, and a good conducting joint is obtained. One claim.

20,968/08. **Recording Telephone Calls.** D. Sinclair and W. Aitken (British Insulated & Helsby Cables, Ltd.). A check delivering mechanism combined with the subscriber's instrument is operated electrically from the exchange directly the called subscriber uses his instrument. A mechanism in the cord circuit for effecting this operation, and controlled by the exchange operator, is described. Eleven claims, eleven figures.

21,089/08. **Surface-contact Systems.** W. M. Mordey. To prevent the formation of arcs between the contact piece and the conductor when there is leakage over the road surface, a condenser is connected permanently in shunt across the contacts of the switch, or between the skate and a contact brush, which touches the stud just left or being left. Several alternative arrangements are described. Nine claims, five figures.

21,580/08. **Flywheel Load Equaliser.** Akt.-Ges., Brown, Boveri & Cie. A three-phase commutator motor is connected in cascade with an induction motor, to which is coupled the flywheel. An automatic device controls the field of the commutator motor, so that the main motor takes up or gives out energy to the line in accordance with the load. Four claims, three figures.

23,705/08. **Line Insulator.** W. Copeland. To obviate the use of binding wires, the insulator itself is formed in two parts—a porcelain body and a slotted metal cap. The wire passes through the slots, and is held in a groove between the two parts, which are screwed together by a central stud bolt independent of the supporting pin. Besides securing the wire, the metal cap protects the insulator against stones. Two claims, five figures.

27,303/08. **Arc-lamp Mechanism.** C. E. G. Gilbert. A toothed wheel on the drum over which the carbons are supported, is engaged by two independent pawls alternately. These are so actuated by the lamp mechanism lever that a step-by-step feed is obtained. To allow free approach of the carbons, both pawls are released simultaneously. Three claims, two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.
Names in italics indicate communicators of inventions from abroad.
Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: Audibert [Vapour-lamp devices] 1,706/09; Walters [Stage lamps] 15,552/09; Carbone, 17,448/09; Siemens Schuckertwerke Ges. [Flame arc lamps] 18,328/09.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Annacker [Transformer distribution system] 21,955/08; Witzenmann [Machines for armouring cables] 27,743/08.

Dynamos, Motors, and Transformers: Boult (*Felten & Guilleaume-Lahmeyerwerke Akt.-Ges.*) [Insulation of machines] 19,263/08; Stansfield and Hatt [Compensating variation in resistance of field coils, &c.] 22,159/08; Siemens & Halske Akt.-Ges. [Insulating former-wound coils] 16,985/09.

Electric Ignition: Bell, 195/09.

Electrometallurgy and Electrochemistry: Smith and Deakin [Electro-deposition of metals] 21,687/08; Walker and Pinson [Electroplating] 12,482/09.

Storage Batteries: Nalder Bros. & Thompson, Ltd., and Nalder [Automatic switch] 23,118/08.

Switchgear, Fuses, and Fittings: Wilkinson [Limit switch] 21,779/08; West [Motor controllers] 25,721/08; Fontecha [Polyphase safety devices] 26,274/08; Birchall [Iron-clad switchgear] 1,675/09; Conner [Relay] 5,145/09; Mygatt [Lamp shades] 9,879/09; Electric & Ordnance Accessories Co., Garner and Collins [Time-limit relay] 15,270/09.

Telephony and Telegraphy: Boult (*International Telechrometer Co.*) [Telephonic apparatus] 1,548/09.

Traction: Szidon [Indicating approach of vehicles at crossings, &c.] 1,058/09; Munro and Railless Electric Traction Co. [Traction system] 1,078/09; Price [Signalling mechanism] 6,290/09; Lake (*European Brake Shoe Co.*) [Brake shoes] 11,456/09.

Miscellaneous: Murphy [Rectifier] 21,366/08; Ritterhaus and Bautze [X-ray tubes] 21,577/08; Parker-Haigh [Marine electric steering gear] 22,880/08; Murday [Secondary clocks] 24,583/08; O'Brien (*Radium-Licht-Reklame Ges.*) [Advertising sign] 5,512/09; Newstetter [Automatic generating systems] 10,198/09; Willing [Flash signalling] 11,945/09; Siemens & Halske Akt.-Ges. [Signalling] 14,213/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: Lamme [Machines] 19,392/09; Heyland [Short-circuiting device for A.-C. motors] 22,932/09.
Meters: Siemens & Halske Akt.-Ges., 22,922/09.
Miscellaneous: Podszus [Vapourising device] 22,827/09.

Patent Restored

24,170/04. **Boiler Cleaning.** A. R. Raymer. This patent, which relates to a method of cleaning boilers while under steam pressure, and which became void owing to the non-payment of the renewal fee, has been restored.

Opposition to Grant of Patents

4,339/08. **Magneto-Generator.** T. Wardell. In spite of opposition, a patent has been granted on this application. The specification was abstracted in Electrical Engineering, June 24th, 1909, page 594.

17,438/08. **Tungsten-Nickel Alloy.** Siemens & Halske Akt.-Ges. Opposition having been unsuccessful, the grant of this patent has been allowed. The process it covers was described in Electrical Engineering, April 29th, 1909, page 406.

25,854/08. **Manufacture of Metal Filaments.** Siemens & Halske Akt.-Ges. A patent has been granted on this application in spite of opposition. An abstract of the process covered appeared in Electrical Engineering, June 3rd, 1909, page 519.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

21,283 of November 9th, 1895. **Electrolytic Apparatus.** A. S. Elmore (*J. O. S. Elmore, India*). To effect rapid deposition of metals, a large volume of the electrolyte is forced to flow through narrow spaces between the anodes and the cathodes, and a very high current density is employed.

21,357 of November 11th, 1895. **Multiple Telegraphy and Telephony.** E. J. P. Mercadier and H. R. J. Pierquin. A relay and other apparatus for use in multiple systems of telegraphy and telephony are described. The relay consists of a telephone with differential windings, and a spring-arm carbon contact-piece. The latter is suspended so as to touch the vertical diaphragm of the telephone at its centre. Special connections of induction coils and condensers are also described.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: Crompton & Co. and A. J. Hudson, 14,615/05.
Distribution Systems, &c.: M. Ferguson [Tubular metal poles for overhead wires] 15,701/02; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Automatic devices for cutting out faulty feeders] 15,632/04.
Dynamos, &c.: Allgemeine Elektricitäts Ges. [Single-phase commutator motor] 14,567/05.
Electric Ignition: S. Bullock [Sparking plug] 14,323/05.
Electrometallurgy: P. Girod [Furnaces] 14,333/05.
Incandescent Lamps: British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Caps] 14,491/05.
Instruments & Meters: G. Harrison (*Electric Railway Improvement Co., U.S.A.*) [Protection of instruments] 14,465/05.
Storage Batteries: C. de Sedneff [Plates] 15,807/02; C. Vellino [Casting plates under pressure] 12,183/04.
Switchgear, &c.: Crompton & Co. and R. C. Harris [Overload cut-out] 15,618/04; Electric & Ordnance Accessories Co., R. F. Hall, and J. R. Garner [Crane controller] 14,345/05; L. K. Job [Thermal "Flasher"] 14,471/05.
Telephony & Telegraphy: W. P. Thompson (*Ges. für Drahtlose Telegraphie*) [Portable wireless aerial] 14,221/05; H. Oppenheimer (*Akt.-Ges. Mix und Genest*) [Annunciator] 14,457/05.
Traction: J. H. F. Bale [Trolley pole head] 14,049/01; A. J. Boult (*J. D. Price and A. C. Miller, U.S.A.*) [Signalling] 15,576/02; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Brakes] 15,466/04; M. J. Sexton [Tram-rail cleaner] 15,513/04; Siemens Bros. & Co. (*Siemens Schuckertwerke Ges.*) [Brake air-pumps] 14,208/05, and [Feeder boosters] 14,209/05; British Thomson-Houston Co. (*General Electric Co., U.S.A.*, [Mounting motors directly on axle] 14,222/05; E. A. Mitchell and Dolter Electric Traction, Ltd. [Surface-contact systems] 14,297/05.
Miscellaneous: J. O. Heinze [Induction coil] 23,492/02; J. Maclean [Feed gear for portable drills] 14,168/05.

THE A.E.G. STEAM TURBINE

THE following particulars of the steam turbine developed by the Allgemeine Elektricitäts-Ges. of Berlin, and supplied in this country by the Electrical Co., Ltd. (121 Charing Cross Road, London, W.C.), are of interest. The turbine is of the impulse type, in which all the drop of pressure takes place in the nozzles. Leaving the nozzle, the steam jet flows axially through radial blades, and, changing its direction in the stationary vanes, traverses a second row of blades in the same wheel. A section through a wheel, showing the two moving blades and the stationary blade, is given in Fig. 2. Fairly large clearances are permissible, hence there is little risk of damage due to deformation of the casing due to expansion. A nozzle is illustrated in Fig. 1. These are made of bronze or nickel steel, while in cases where highly superheated steam is employed, they are made of a special grade of cast iron. The form of nozzle used in this case is shown in Fig. 3. The 1,500-h.p. turbine, at 3,000 r.p.m., converts the whole energy of the steam from, say, 200 lbs. pressure 190° Fahr. superheat, down to condenser pressure, in two pressure stages. It has two chambers, each with a single wheel with two rows of blades. In the first set of nozzles the steam is transformed into a velocity jet at about atmospheric pressure, while in the second set of nozzles the steam expands to condenser pressure and flows to the condenser after losing its velocity in the second set of blades. The design of A.E.G. turbines for similar speeds is the same for all sizes. A high degree of superheat is permissible, since only the high-pressure nozzles are subjected to the high temperature. A 4,000-kw. A.E.G. turbine running at 180 lbs. per sq. in. pressure, 275° Fahr. superheat, has a steam consumption of 11·9 lbs. per kw.-hour. This figure was obtained with the three-phase set installed in the Rummelsburg Electricity Works, Berlin.

FIG. 1.—VIEWS OF NOZZLE.

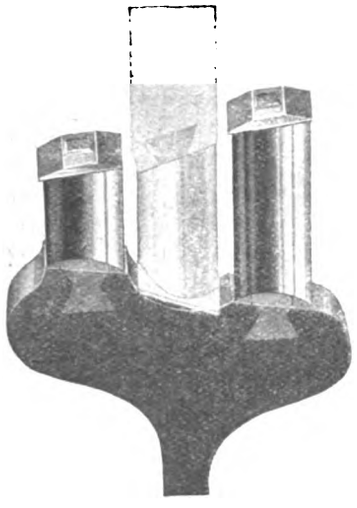

FIG. 2.—WHEEL-RIM, WITH BLADES.

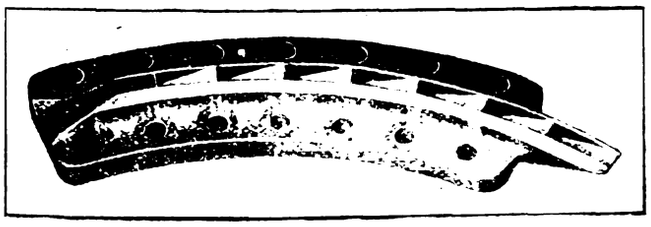

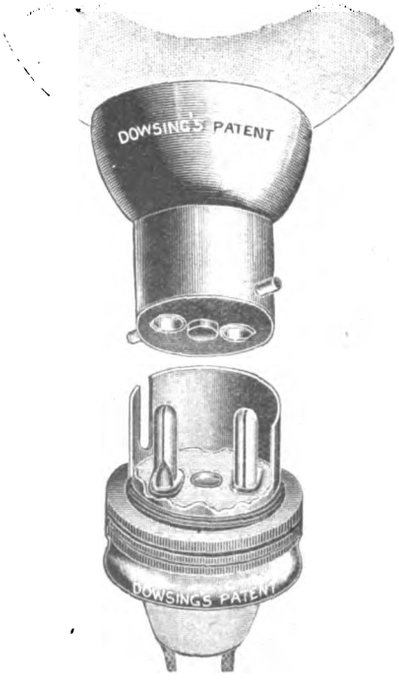

FIG. 3.—NOZZLES FOR HIGHLY SUPERHEATED STEAM.

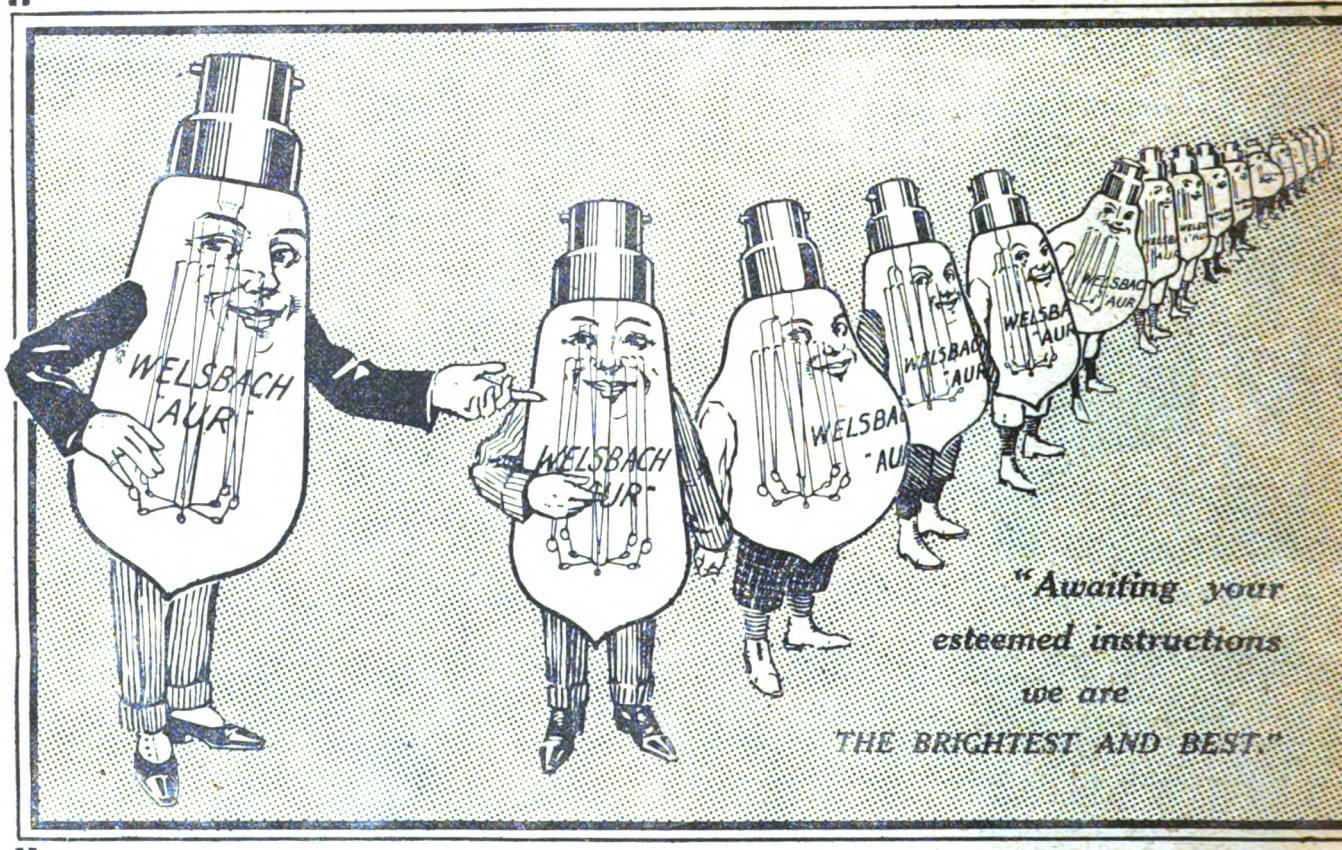
The standard speeds for 50-cycle turbo-alternator sets are 3,000 r.p.m. up to 2,000 k.v.a., and for larger sizes 1,500 and 1,000 r.p.m. For continuous-current sets, the speeds are 800 r.p.m. above 750 kw., 1,200 r.p.m. for sets between 500 and 750 kw., and so on, until for sets below 40 kw. the speed is 4,000 r.p.m. The casing of the slow-speed turbines is constructed in three parts, the end cover, and the top and bottom casings, which are arranged to form chambers according to the number of pressure stages required. The casing of the high-speed turbines is not made in two parts, however, but in segments which are threaded on to the shaft one after another and bolted together axially. The blade wheels are made of nickel steel, and have dove-tail grooves for receiving the blades, as shown in Fig. 2. The boss of each wheel is bored taper to fit a corresponding cone on the shaft. The blades themselves are of bronze or nickel steel, and are rivetted in groups to circumferential strips. A governor of the vertical centrifugal type is employed, and this controls a double-beat throttle valve through a piston worked by oil pressure. An automatic nozzle control is provided for turbines subject to intermittent loads, as in rolling mill and colliery winding plants. Besides the above patterns of turbines, the Electrical Co. supply a number of special types including back-pressure exhaust, reducing, low pressure, and mixed pressure turbines.

A NEW LAMP-HOLDER FOR RADIATOR LAMPS



THE Dowsing Radiant Heat Co., Ltd. (24 Bridge Row, E.C.), have designed a lamp-holder for use particularly with Dowsing radiator lamps. As seen in the illustration below, the spring buffers of the ordinary lamp-holders are replaced by fixed pins, which pass into metal sleeves or sockets let into the cap of the lamp, thus securing an all-round maximum contact, and avoiding the possibility of local heating or arcing. The makers state that with the new lamp-holder and cap about ¼ sq. in. of contact area is obtained, as compared with about ⅛ sq. in. with the ordinary holder and cap. A new price list, which the firm have just published, describes a large selection of radiators in Jacobean, Elizabethan, Sheraton, Adams, and other styles, and also a 2-kw. "radio-convertor." This contains four luminous heat lamps of the ordinary type, and also non-luminous heaters, so that both direct radiation and convection currents are employed in heating the room.

Welsbach Electric Light

Metallic Filament Lamps.

ORDER NOW for prompt delivery.

Any size, any shape, any candle power, any voltage indicated in the Welsbach list.

Every assistance is given by the Welsbach Company to the trade and safe delivery is guaranteed in dozens. The great strength and superiority of the Metallic Filament enables the Welsbach Company to give this unequalled guarantee.

If handled with ordinary care Welsbach Lamps are practically as immune from breakage as the old Carbon Filament types. Longest life with lowest consumption and highest efficiency are other important points.

See the Welsbach Company's name and registered trade mark "AUR" on every lamp.

Full particulars on application to—

THE ELECTRIC LIGHTING SECTION,
The Welsbach Incandescent Gas Light Co., Limited.

MUSIC HALL ELECTRICITY

AN action was commenced on Monday before Mr. Justice Darling in the King's Bench Division, in which Mr. C. H. Irving sued Samuel Murphy Bodie, well known on the music-hall stage as "Dr. Walford Bodie," for the recovery of £1,000 paid as premium three years ago, to learn "Dr." Bodie's profession. The case has created a good deal of interest, and has been the cause of considerable merriment in court, for "Dr." Bodie describes himself as a hypnotist and mesmerist, a bloodless surgeon, and a medical electrician. He has admitted, however, that he is not a qualified medical man, either in this or any other country. It appears that Irving became acquainted with Bodie in 1903, and in 1906 signed an agreement to pay him £1,000 to serve as a pupil for three years at a salary of £2 10s. per week. "Dr." Bodie in his performances upon the music-hall stage claims to cure persons of paralysis and similar complaints, whilst under hypnotic influence, and also presents certain spectacular electrical effects. He also claimed to be able to withstand a higher voltage than any other person living. The whole of the performance, however, the plaintiff alleged to be a fraud, and it is for this reason that he asked for the return of his premium. The agreement stipulates for a penalty of £500 in the case of the non-fulfilment of the contract, and defendant counterclaims for this sum.

The evidence of the plaintiff was to the effect that Bodie had with him on his journeys around the country a number of hired men who sat amongst the various audiences and went upon the stage to test Bodie's hypnotic powers. In every case, by pre-arrangement, the hired men knew what to do, and the show was very successful. If a genuine member of the public presented himself he was hustled about and knocked down. In the same way it was alleged that the same "patients" suffering from paralysis were repeatedly "cured" at different music-halls. Another part of the performance was a so-called "cage of death," into which a man, apparently in a cataleptic state, was placed. It was announced to the audience that but for Bodie's influence over the man he would have been killed by the current at 2,000 volts. This "cage" was made to give off sparks, but fireworks were also used to heighten the effect. In fact, the greatest danger was from the latter. The patient was alleged to be one of Bodie's paid servants, who merely pretended to be hypnotised. This "cage of death" afterwards turned out to be, on the evidence of Mr. E. Drevill, of the Medical Supply Association, London, a solenoid similar to those used for high-frequency treatment in hospitals, which are perfectly safe from the point of view of shock. The Medical Supply Association sold Bodie one of these two and a half years ago for ten guineas. Messrs. H. W. Cox & Co., the medical electric apparatus manufacturers, have also sold the defendant a similar machine.

Early in the proceedings Mr. Justice Darling made it clear that the point he intended to leave to the jury was whether the performances were genuine, and not whether undue influence had been used to induce the plaintiff to sign the agreement.

On Tuesday, the evidence of a number of persons suffering from paralysis was heard, and they all declared that "Dr." Bodie's treatment did them no good. Indeed, one or two mentioned that they were ill for several days afterwards. Evidence was also given by one of the hired men, who sat amongst the audience, and went on to the stage, and was subsequently hypnotised. He had been regularly employed by Bodie to do this, but no real hypnotism took place. In the cure of paralytic patients some electrical apparatus was made use of, and one witness said that in his case Bodie rubbed a magnet on the wrong leg; it was the other one which needed treatment. They all said they felt a pricking sensation when the electricity was applied.

For the defence, a number of persons were called who declared that they had been cured by Bodie of paralysis, curvature of the spine, &c., by his electrical and other methods, and they had all been induced to say so whenever publicly "Dr." Bodie made a reappearance in their district. "Dr." Bodie, who commenced his evidence late on Tuesday, said that he had been giving public performances for 23 years, but for three years prior to that he was inspector and electrician to the National Telephone Co. in Aberdeen.

During the day counsel for the defence, Mr. A. Powell, K.C., offered to bring all "Dr." Bodie's apparatus into court, and for the defendant to demonstrate publicly, in the presence of a qualified electrician, that he was able to withstand the high voltages mentioned.

Bodie continued his evidence yesterday, when he admitted that numerous statements published in his book and in advertisements were untrue. It was then arranged that he should demonstrate that afternoon privately before the jury and an expert electrician his capability of sustaining an intermittent current at 60,000 volts from what he described as a 12-inch induction coil. It would not, he said, be a high-frequency current.

The case is still proceeding as we go to press.

LOCAL NOTES

ABERDEEN: *Medical Inspection of Tramway Employees.*—The Tramway Manager recommends the appointment of a special medical officer for the Tramways Department, whose duty it will be to medically inspect the employees before they are taken on. At present the men have to bring a doctor's certificate of fitness with them when applying for employment.

Supply for Tramways.—The Electricity Department recommend an enforcement of the terms of the award in connection with the supply of electrical energy to the Aberdeen Suburban Tramways Co.

ACTON: *Electric Lighting.*—A letter has been sent to the Metropolitan Electric Supply Co. by the Ratepayers' Association, asking whether the company would agree to cancel the existing agreements and take over the undertaking without special remuneration; whether they will provide the necessary extensions; whether they will provide street lighting at 1d. per unit; and whether, in the event of the undertaking being acquired within six months, the amount payable to the company in respect of capital expenditure incurred by them on behalf of the Council, would be payable. The company have replied in the affirmative to all the questions with the exception of the last. In this case, the answer is satisfactory, inasmuch as they state the sum in question would not be payable under the proposed circumstances.

ARGENTINE: *Buenos Aires: Tube Railways.*—The Senate has passed the Western Railway Companies Tube Railway Bill. Another proposal for the construction of tube railways is from Messrs. Otto Francke & Co., which run in a different direction across the City. This has also been approved by the Senate. According to the *Review of the River Plate*, the Buenos Aires municipality objects to the sanctions on the part of the Senate, as they hold the view that the subsoil of the city belongs to the city authorities.

AUSTRALIA: *Sydney: Electric Lighting Charges.*—The City Council have had under consideration a proposal for restricted hour charging. The recommendation was to charge 1½d. per unit to consumers disconnected between 4 and 7 p.m. during April, May, June, July, August, and September, and for three hours each day to be agreed between the consumer and the Council for the remainder of the year. These terms, however, are only to be offered to consumers of 27,000 units per annum and upwards. The matter has been referred back to the Electric Lighting Committee.

BATH: *Somerset Power Co.*—The Board of Trade have issued an order for the cession of the powers of the Somerset & District Electric Power Co. within the city of Bath.

CAERPHILLY: *Transfer of Provisional Order.*—It is intended by the Council to transfer their Electric Lighting Provisional Order to the South Wales Electrical Power Distribution Co., Ltd.

DERBY: *Tramway Accounts.*—The report of the tramway manager for the year to March 31st shows a net profit of £3,735 against £4,804 last year. The number of passengers carried was 9,909,359, an increase of over 1,000,000 compared with the previous year.

LEEDS: *Trolley Omnibuses.*—With regard to the proposal to use trolley omnibuses from the City Square to Farnley, an endeavour is to be made to induce the Board of Trade to grant a licence for this purpose, in order to obviate the delay and expense of promoting a special Bill in Parliament. A deputation is to wait upon the Board of Trade.

LONDON: *City of London Tramways.*—At a meeting of the City of London Tradesmen's Club on Thursday, a resolution was carried, after a debate on the question, to the effect that the time had now arrived when the northern and southern tramway system should be linked up. During the debate, tramways were proposed along New Bridge Street; over Southwark Bridge; and another along Queen Victoria Street.

London County Council: Tramway Employees.—A scheme has been drawn up for the establishment of conciliation boards for the settlement of questions affecting the employees of the tramways department.

Kensington: Tramways.—At a ratepayers meeting last week, held under the presidency of the Mayor, it was decided to petition the Borough Council to oppose the construction of tramways in North Kensington, to connect Wood Lane with Harrow Road. Mr. Whittaker Thompson, a former chairman of the Highways Committee of the L.C.C., spoke at the meeting, and regretted the decision come to, as the tramways proposed were intended to form an important part in the County Council system.

Lambeth: Supply outside Area.—It has been brought to the notice of the London County Council that the South London Electric Supply Corporation, Ltd., are supplying certain consumers beyond their area. Technically this is illegal, but the Council propose to take no action in the matter.

Digitized by Google

Paddington: Electric Supply.—The Highways Committee of the London County Council recommend that no action at the present time be taken to obtain a reduction in the prices charged by the Metropolitan Electric Supply Co. for electrical energy in Paddington. It will be remembered that the company proposed to transfer their Amberley Road station to the Willesden power-house, and in consideration of this, the Paddington Borough Council asked for a reduction in the prices now charged in the borough. The company at first agreed to this, but later found it impossible to make any reduction owing to the increased use of metal filament lamps.

MACCLESFIELD: *Electric Lighting.*—The Board of Trade have threatened to revoke the Council's electric lighting order, and in consequence the Council have instructed the Gas Committee to prepare plans and estimates for putting the order into force.

MANSFIELD: *Gas Explosions.*—Owing to explosions in cable conduits which damaged the cables, the whole of the tramways of the Mansfield & District Light Railway system were unable to run on Wednesday last week. In some instances, not only the lead covering, but the cable itself, was burnt away.

MUSSELBURGH: *Tramway Fares.*—The Musselburgh & District Electric Lighting & Traction Co. have refused to revert to the system of ½d. fares formerly in use. They have informed the Council that whilst this was in operation, a loss of between £300 and £400 per annum was incurred. The Company offer to introduce 1½d. fares, but refuse to concede more, for the reason that the preference shareholders during the past two years have only received 2 per cent. dividend, whilst the ordinary shareholders have never received any dividends at all.

NEWCASTLE: *Condition of Tramway Undertaking.*—A report has been prepared by Mr. E. Hatton, the general manager of the Corporation Tramways, dealing with the general position of the undertaking. The financial position during the past year has become very unsatisfactory, and Mr. Hatton calls attention in this connection to the exceptional facilities offered by the ½d. fares, in which he suggests modification. He also suggests a revision of the stages of several routes. Mr. Hatton concludes by recommending a reduction in working expenses as the other alternative at present. Should this fail to bring about the desired result, the ratepayers, he says, will then know that an increase in fares is inevitable, if the necessary sums are to be set aside annually for renewals and depreciation. The consideration of the report is postponed for a fortnight, when a proposal to allow advertisements to appear on the cars will be made.

NEWCASTLE (IRELAND): *Electric Lighting.*—A Lewisham firm have offered terms to the Council for erecting an electricity works, but it has been pointed out to them that it is now too late to apply for a Provisional Order this year. The Council are to consider the feasibility of preparing a scheme themselves.

NEWPORT: *Tramways.*—The receipts from the tramway undertaking for the year just ended amounted to £35,531, against £36,162 last year. After meeting capital charges, however, there is a net profit of £1,662.

Electric Supply.—There is a loss of about £1,300 upon the electric lighting undertaking for the past year, in spite of an increase in revenue and a diminution in works costs. The loss is mainly attributed to the extended use of metal filament lamps.

Trailer Cars.—The Board of Trade have notified the Corporation that they cannot at present give their consent to the use of trailer cars on the tramway system, but express their willingness to give the matter further consideration if it is desired. The Corporation have decided to place additional information before the Board of Trade.

PORTSMOUTH: *Electric Driving.*—The *Naval and Military Record* states that a start has been made with the conversion to electric driving of the machinery in the dockyards at Portsmouth. No. 1 shipbuilding shop is the first to be dealt with.

PRESTON: *Tramway Accounts.*—The accounts of the Tramways Department for the year to March 31st, 1909, show total receipts amounting to £38,834, compared with £38,763 for the previous year. The gross profit amounted to £14,368, compared with £15,801. After meeting capital charges there is a balance of £4,439, against £4,394, and after deducting the cost of five new top covers there is a balance of £3,760, which is placed to reserve, compared with £3,195 in the previous year.

ST. ANNE'S-ON-SEA: *The Electrical Exhibition.*—A very successful Electrical Exhibition has been organised by the electricity department of the Corporation. Demonstrations and lectures of cooking by electricity are being given, and the exhibition contains a very complete show of all classes of electrical apparatus for domestic purposes.

SOUTHEND: *Light Railways.*—The Board of Trade have confirmed the Southend-on-Sea Light Railways Order, 1909, reviving the powers granted by the Southend-on-Sea and District Light Railways (Extensions) Order, 1904, and extending the periods for the compulsory purchase of lands, &c.

SPALDING: *Electric Lighting.*—Inquiries have shown that there are only a few people likely to take electric light if installed. The Council have therefore decided to ask the Board of Trade for a further extension of time for putting their Provisional Order into force.

SWANSEA: *Electricity Accounts.*—In reporting upon the accounts of the electricity department for the year to March 31st, 1909, the elective auditors, commenting upon the profit of £1,748, congratulate the Electric Lighting Committee for resisting the attempt made to absorb this sum into the general rate, as it is absolutely necessary to make ample provision for reserve, which the auditors are sorry to see is not provided for in the accounts. They also suggest that the time has arrived for charging meter rents. There are over 1,300 meters in use, and a rental of 1s. 6d. per quarter, they point out, would produce a revenue of £400 per annum

TURKEY: *Electric Lighting.*—It is stated that specifications for an electric lighting plant in Constantinople are shortly to be prepared. There is also a proposal to convert the present horse tramways to electric traction.

WILLESDEN: *Electricity Accounts.*—The accounts for the year to March 31st show a net profit of £320, a decrease of £405 as compared with the previous year. Mr. Bruce, the Council's electrical engineer, reports that the change over to metal filament lamps has not been very rapid in Willesden, and the revenue obtained from new consumers during the year more than counterbalances the reduction in revenue received from the older consumers. A new rotary converter of 300-kw. capacity, installed by the British Westinghouse Manufacturing Co., showed efficiencies above the guarantees in every way.

WIMBLEDON: *Damages for Non-completion of Contract.*—The Borough Electrical Engineer reports that the 1,000 kw. turbo-alternator supplied by Messrs. J. Howden & Co., Ltd., was completed and in working order on October 7th, whereas the date for the completion of the work was April 30th last. The liquidated damages payable by the company for the non-completion of their contract within the time specified amounted to £1,673 5s. The Council have resolved to pay Messrs. Howden & Co. £3,637 10s., being 50 per cent. of the contract price, and to defer the consideration of the question of enforcing payment of the damages.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BIRMINGHAM.—Messrs. Cadbury Bros., Ltd., of Bournville, invite tenders for stores, including electric cables, electric lamps, and sundries. Applications for tender forms not later than November 6th.

CLEETHORPES.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £4,000 for electric lighting purposes.

DUNDALK.—The Council are about to spend £20,000 upon electrical plant. Tenders are invited for a loan of this amount, repayable in 25 years.

LONDON: *Hammersmith.*—The Finance Committee of the L.C.C. recommend a loan of £10,000 for mains, transformers, house services, and meters.

Woolwich.—The Finance Committee of the L.C.C. recommend a loan of £2,604 for mechanical stokers, coal-handling plant, and cable ducts.

MIDDLETON.—A loan of £3,000 for cable extensions is to be applied for.

NAVAN (IRELAND).—The scheme for the electric lighting of the Union, recently formulated by Mr. A. Scott, of Dublin, has been submitted to the L.G.B. The Urban District Council is applying to the Board of Trade for a provisional order empowering the Council to supply electricity in their jurisdiction for public and private purposes.

OLDHAM.—In connection with an application by a large firm for a supply of electricity for power purposes, the electrical engineer states that it will be necessary to consider the question of extending the power station.

TURKEY.—The Acting British Consul-General at Constantinople has forwarded a copy of the convention and conditions of tender for the installation of electric light and power, and for the construction of an electric tramway, at Broussa. Sealed tenders, addressed to the Municipality of Broussa, will be received up to December 13th. In the case of Turkish municipal contracts, it is understood that it is practically impossible for a British firm to tender with success except through a thoroughly competent agent on the spot. A list of British firms established at Constantinople may be obtained, and the documents forwarded by the Acting Consul-General may be seen, by British firms interested on application at the Commercial Intelligence Branch of the Board of Trade, London.

Miscellaneous

AUSTRALIA.—H.M. Trade Commissioner for Australia, says the *Board of Trade Journal*, reports that tenders will be received by the Deputy Postmaster-General at Melbourne, by November 9th, for the supply of electrical material, including ampere-meters, dry cells, and switchboards. It will be observed that the limited time for receipt of tenders will not permit of their

Digitized by Google

being despatched by post, and the above intimation is therefore only of use to those firms having agents in Australia whom they can instruct by cable. Tender forms, &c., may be obtained, and preliminary deposits paid, at the Australian Commonwealth Offices in London, 72 Victoria Street, S.W. Copies of the specifications, conditions, &c., may be seen by British makers interested on application at the Commercial Intelligence Branch of the Board of Trade.

BODMIN.—The Wadebridge Electric Light Co. are placing a proposal before the Council for the erection of electricity works. The matter has been referred to the Lighting Committee.

DUBLIN.—The Dublin United Tramways Co. require general stores, including electric supplies. Particulars from the Secretary, and tenders by November 13th.

JAPAN.—H.M. Commercial Attaché at Yokohama reports that a company is to be formed, with a capital of 2,000,000 yen (about £204,000), to construct and work an electric railway. The railway is to run for a distance of some nine miles in the suburbs of Tokio, and is to be connected with the Tokio Railway at Otsuka.

LONDON: *London County Council.*—The Highways Committee recommend an expenditure of £44,070 upon the construction of tramways from Streatham High Road to Mitcham Road, and £5,700 upon tramways in Wimbledon Road. An expenditure of £68,020 is also recommended for the reconstruction of a further portion of the Woolwich and South-East London tramways.

An expenditure of £200 is recommended upon the purchase of 14 car body trucks for use at the central car repair depôt.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Fire station, Parnell Road, Bow. Builder, H. L. Holloway, Church Street, Deptford, S.E.

N.W.—St. Jude's Church, Hampstead (£12,000). Architect, E. L. Lutyens, 29 Bloomsbury Square, W.C.

Schools, Haverstock Hill (£11,842). Builders, McCormick & Sons, Ltd., Northampton Street, Essex Road.

S.E.—Enlargement and alterations of L.C.C. Woolwich Fire Station. Builders, William Johnson & Co., Ltd., Wandsworth, S.W.

S.W.—Extensive alterations to Polytechnic, Regent Street, S.W. L. H. Harris.

Residential hotel with shops under, on site of St. George's (Hanover Square) Hall, Mount Street, S.W. Hammersley Kennedy & Co., 88-90 Chancery Lane, W.C.

PROVINCES.

AYR.—Business premises, 244 and 248 High Street (£3,000). Architect, W. Cowie, Alloway Chambers, 239 High Street.

BANGOR.—Hospital (£3,000). Architects, Young and McKenzie, Scottish Buildings, Belfast. Builders, J. and R. Thompson, Roden Street, Belfast.

BRIGHOUSE.—Salvation Army Hall. Architect, A. Gordon, 97 Queen Victoria Street, London, E.C.

BIRMINGHAM.—Laundry at workhouse (£3,447). Architects, W. H. Ward, Paradise Street, Birmingham. Builder, E. Crowder, Birmingham.

DUNDEE.—School board offices (£6,000). Architects, J. H. Langlards, 81 Murrayfate, Dundee.

EDINBURGH.—New laboratories (£3,500). V. T. Oldrieve, H.M.O.W., Edinburgh.

GRIMSBY.—School, Strand Street (£11,200). Architect, H. C. Scaping, Court Chambers, Grimsby. Builder, W. Kirtons, Grimsby.

HAMILTON.—Extensions to Fever Hospital (£6,500). Cullem Lockhead & Brown, Architects, Hamilton.

HULL.—Training College (£33,350). Architects, Crouch, Butler, & Savage, 39 Newhall Street, Birmingham.

KEIGHLEY.—Additions to Post Office (£2,500). Builders, Wrights, Ltd., Leeds.

LANCASHIRE.—Erection or enlargement of eighteen secondary and technical schools. County Architect, County Offices, Preston.

LIVERPOOL.—Church and Church house (£15,000). Architects, Bradbury & Son, Liverpool. Builders, Haigh & Pilling, Walnough Street, Liverpool.

MEXBOROUGH.—Tenders are invited for the wiring of a new rink. Applications to Mr. J. Willis, 100 High Street.

MIDDLETON.—Extensions, Tanfield Mills (£5,000). Architects, Sellers, Son, & Orrell, Union Chambers, Bury.

MANCHESTER.—School. Governors, Manchester Ladies' Jubilee School for Girls.

PERTH.—New Sessions House Buildings (£3,000). R. McKillop, Borough Surveyor, Perth.

STOCKTON.—Additions to Dean Bank School (£2,400). Builder, Mr. Cook, Stockton.

TENDERS RECEIVED AND ACCEPTED

BARKING.—The Council have received the following tenders for the supply of low-tension service cables:—Western Electric Co. (accepted), £78 5s.; Siemens Bros. & Co., Ltd., £80 2s. 6d.; W. T. Henley's Telegraph Works Co., Ltd., £82 7s.; Johnson & Phillips, Ltd., £82 7s. 6d.; W. T. Glover & Co., Ltd., £82 10s.; British Insulated & Helsby Cables, Ltd., £83 15s.; Union Cable Co., Ltd. (foreign cable), £65 8s.; Electrical Co., Ltd. (foreign cable), £62 10s.

BENTLEY (Doncaster).—A contract for a scheme of main sewerage of Bentley Colliery and Rostall, Doncaster, has been let to Messrs. C. Bushby & Son, of Leeds. The work, which has been designed by Messrs. D. Balfour & Son, of Newcastle-on-Tyne and London, includes a pumping station, each of the storage tanks having a capacity of 2,000 gallons, from which the sewage will be pumped by electrically-driven centrifugal pumps.

BRUMBY AND FRODINGHAM.—The tender of Messrs. Reid, Frans & Co., of Newcastle-on-Tyne, has been accepted for public electric lighting at £279.

SOUTH AFRICA.—The following tenders have been accepted by the Johannesburg Corporation:—Tramway spares—Dick, Kerr & Co.; feeder pillars, cable and overhead sundries, &c.—The Telegraph Manufacturing Co.; cable—Henley (S.A.) Telegraph Co.; transformers—Western Electric Co.

TURKEY.—With reference to the question of the Constantinople Telephone Concession, *The Financial News* states that among the firms which have submitted tenders for the construction of the telephone installation are the following: Antwerp Telephone Company, Antwerp; Deutsche Telephonwerke, Berlin; Siemens and Halske, Berlin; Milde and Fils, Paris; Brenon, Paris; Société Générale de Télégraphic de l'Est, Constanka; Skon Skirakian, Constantinople; and several English firms. No decision has been arrived at yet by the Turkish Government, but it is said that the offer of a French firm is likely to be accepted.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 5s. to £59 15s. per ton (last week, £58 5s. to £58 15s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The statement of affairs in the bankruptcy of P. E. Butler, before the London Bankruptcy Court last week, stated that in May, 1903, he promoted the Electric Lamp Renovating Co., Ltd. This company, together with a number of others of a non-electrical character, failed, and to this the debtor attributed his position.

Mr. E. Goodman, electrical engineer, 30 Hertford Street, Coventry, has been adjudicated bankrupt.

SIEMENS BROS. DYNAMO WORKS, LTD.—This firm have opened a new show-room and supplies department at 39 Upper Thames Street, London, E.C., particulars of which will be found elsewhere in this issue.

A NEW FIRM.—Mr. A. Feld and Mr. F. W. Sichtermann have resigned their positions as departmental managers in the Electrical Co., Ltd. (A. E. G. Berlin), and have established themselves as suppliers of all electrical materials for lighting and power plants. The style of the firm is Feld Bros. & Co., Ltd., 25 Budge Row, E.C. (Telephone, 1697 London Wall). They are putting on the market a new metal filament lamp which they are calling the "Field" lamp. It is of British manufacture, and, we are informed, embodies some improvements, especially in the high-voltage pattern.

APPOINTMENTS AND PERSONAL NOTES

The Guardians of Oxbridge Union require a working electrical engineer and fitter to take charge of the electrical installation at the workhouse. Wages, 35s. per week, with house and light. Applications by November 10th to the Clerk, Poor Law Offices, Oxbridge.

A teacher of electrical engineering is required at the City of Dublin Municipal Technical School at a salary of £14 per month. Applications to the Secretary by November 9th.

Wireless Telegraphy.—It is stated that the French wireless telegraph stations at Toulon, Oran, and Bizerta, will be put into operation this week by the military authorities. With the opening of these stations, the French wireless telegraph system, having for its centre the Eiffel Tower, will be complete.—The French Government are also erecting a station at Rufisque, in Senegal, and this will shortly be in communication with Eiffel Tower.—Experiments are to be carried out between the Eiffel Tower wireless station and New York. The *Figaro* states that if the results are satisfactory, arrangements may be made for the interchange of mutual good wishes on January 1st by President Taft and President Fallières.

COMPANIES' MEETINGS AND REPORTS

MONTE VIDEO TELEPHONE CO.—The report for the year to July 31st shows a net profit of £19,931, to which is added £2,796 brought forward. After placing £11,000 to depreciation, a dividend of 6 per cent. on the ordinary shares is recommended for the year, carrying forward £3,042.

At the meeting last week, the report and accounts were adopted. With regard to the suggestion that the Government should start a telephone system, the Chairman said that neither the public nor the Government would gain by this, and the company were seeking to obtain a concession in order that they could give an up-to-date service at a moderate cost.

ELECTROLYTIC ALKALI CO.—After allowing for depreciation and debenture interest, &c., there is a balance of £22,174, including a sum brought forward. There are three years' dividends due on the preference shares, and the directors propose to pay one year of this, and to carry forward £15,177.

At the annual meeting on Thursday, the report and accounts were adopted. The Chairman stated that although the amount in hand was sufficient for meeting all the arrears of the preference dividends, the Board thought it wise, in the present bad state of trade, to recommend the payment of one year only.

CORDOBA LIGHT, POWER & TRACTION CO.—The report to September 30th last shows a profit, after meeting all charges, including interest on debenture stock, of £13,410. The directors recommend a dividend at the rate of 2 per cent. (less income-tax) and that the balance of £5,191 be carried forward. To supplement the existing water-power generating plant during the periods of heavy load or shortage of water, steam plant of approximately 900 h.p. has been installed, and a further addition of over 1,100 h.p. is on its way out from England.

HURST, NELSON & CO.—The report for the year to July 17th shows a net balance of £10,910, after setting aside £11,903 for depreciation. The 6 per cent. preference dividend is recommended, and a balance of £6,170 carried forward.

ROSARIO ELECTRIC CO.—The net profit for the year to June 30th amounted to £35,014. A dividend of 5s. per share is recommended on the ordinary shares, and 8 per cent. on the second preference shares converted into ordinary shares. After adding £15,000 to the reserve, the sum of £9,282 is carried forward. At the annual meeting on Tuesday, the report and accounts were adopted.

NORWICH ELECTRIC TRAMWAYS CO.—At the annual meeting on Friday, the report and accounts were adopted. After meeting interest on mortgage bonds, there was a profit of £5,318 A dividend of 1¾ per cent. is to be paid, in addition to placing £500 to reserve.

CUBA SUBMARINE TELEGRAPH CO.—At the annual meeting last week, the report and accounts given in our issue for October 21st were adopted.

CLEVELAND & DURHAM ELECTRIC POWER CO.—At the annual meeting last week, the report and accounts given in our last issue were adopted. Mr. Charles Emmott, the chairman of the company, said that trade depression during the year had been reflected in the balance sheet of nearly every industrial undertaking in the north-east district. There were, however, many prospects for the company in the future for the utilisation of electricity in mines, there being about 150 pits in their area, which could be advantageously connected to mains. He thought that he could say from negotiations now proceeding with many very large power users that at the next meeting very much improved results would be shown.

CAPE ELECTRIC TRAMWAYS CO.—The accounts for the year to June 30th show a loss of £2,400.

EASTERN TELEGRAPH CO.—There is an available balance for the half-year to June 30th of £348,155. After meeting mortgage interest and preference dividends, there is a balance of £265,068. The sum of £110,000 is placed to general reserve, and £100,000 to meet interim dividends on the ordinary stock of 1¼ per cent. The sum of £55,068 is carried forward.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH CO.—There is a net profit of £115,838 for the June half-year. After meeting two 1¼ per cent. quarterly dividends, the sum of £58,844 is carried forward.

New 6,000 kw. Generating Set at Manchester Corporation Electricity Works.—Under the heading of Table I. of this article on p. 928 of our last issue, there is a slight inaccuracy with regard to column 3. This gives the actual test results obtained, not with a 27-inch vacuum, but with a vacuum varying from 27·56 inches at 25 per cent. overload to 28·75 inches at quarter load. Columns 4 and 5 are correct as given, namely, the test results corrected to 28-inch vacuum and 140 degrees of superheat.

Proposed L.C.C. Tramways.—The Highways Committee of the London County Council recommend applying for Parliamentary powers for the construction of new tramways in Maida Vale and Canonbury Road, and the reconstruction of existing tramways in Highgate Road, Islington, and Stoke Newington. The total length of line to be dealt with is 14·7 miles of single track, and the estimated cost is £328,695. The conduit system is to be adopted in all cases with the exception of the Maida Vale line.

MISCELLANEOUS CITY NOTES

ELECTRICITY SUPPLY CO. FOR SPAIN.—A petition for the reduction of the capital of this company from £205,000 to £105,000 was heard before Mr. Justice Parker in the Chancery Division of the High Courts on Tuesday. His lordship sanctioned the reduction.

ALUMINIUM CORPORATION.—Meetings of the unsecured creditors, holders of participating preference shares, and ordinary shareholders will be held at Winchester House, Old Broad Street, London, E.C., on November 11th, at 2 p.m., 3 p.m., and 4 p.m. respectively, to consider a scheme of rearrangement. Copies of the latter may be seen at the office of the liquidators, 34 Old Broad Street, London, E.C. The executors of the late Mr. Charles Morrison and Messrs. Wernher, Beit & Co., have also offered to purchase the assets of the company for £80,000.

COMPANIES STRUCK OFF REGISTER.—The names of the following companies have been struck off the register, and are declared dissolved :—Anglo-Iberian Electric Light & Power Co.; Carl Oppermann Electric Carriage Co.; Electric Carriage & Storage Co.; London Electric Supply (Joint Committee).

WEST AFRICAN TELEGRAPH CO.—An interim dividend of 4 per cent. per annum, free of tax, has been declared for the past half-year.

WESTERN TELEGRAPH CO.—A final dividend of 3s. per share, making 6 per cent. for the year to June 30th, is recommended. The sum of £90,000 has been transferred to reserve fund; £5,000 to the maintenance of ships fund; £10,000 to marine insurance fund; and £10,000 to land and buildings depreciation. A bonus of 2s. per share is also recommended.

CITY OF BUENOS AIRES TRAMWAYS CO. (1904).—A dividend of 1s. 3d. per share, less tax, is declared for the September quarter.

NEW COMPANIES

KINETIC CO.—Registered on Oct. 14th, with a capital of £5,000, to take over the business of electrical and general engineers, manufacturers of and dealers in electric, water and other engines and apparatus for blowing organs, air compressors and exhausters, &c., carried on by E. J. Jackson and J. H. Swanton at Lincoln as the Kinetic Co. Private company. Registered office : Rosemary Lane, Lincoln.

CARMARTHEN ELECTRIC SUPPLY CO.—Registered on Oct. 14th, with a capital of £10,000 in £1 shares (5,000 five per cent. preference), to acquire from J. B. Saunders & Co. the benefit of the Carmarthen Electric Lighting Order granted to them under the Electric Lighting Acts, 1882 and 1888, for the supply of electrical energy in Carmarthen, and to carry on the business of electricians, mechanical engineers, suppliers of electricity, &c. Registered office : Salisbury House, London Wall, E.C.

ANGLO-GERMAN WIRELESS SYND.—Registered on Oct. 12th, with a capital of £200 in 1s. shares, to adopt an agreement with Baron Egbert von Lepel, General Baron von Gayl, and Dr. W. Burstyn and others, trading as the Drahtlose Telegraphie-system von Lepel, and to carry on the business of electricians, engineers, battery makers, founders, generators, distributors, and workers of and dealers in electricity, land, submarine, and aerial telegraphy, &c. Minimum cash subscription, £10. Registered office : Audrey House, Ely Place, E.C.

ELECTRIC SMELTING CO.—Registered on Oct. 11th, with a capital of £6,000, to carry on the business of manufacturers of and dealers in machinery for the treatment of ores and the generating of electricity, &c., to acquire the right to use any secret or other information relating to the treatment and reduction of ores, or relating to magnetic separators, and to adopt an agreement with M. Ruthenburg. Private company. Registered by Ingle, Holmes, Sons, and Pott, Capel House, E.C.

WEMBLEY HEATING CO.—Registered on Oct. 13th, with a capital of £2,000, to carry on the business of heating, ventilating, domestic and electrical engineers, contractors, art metal workers, &c. Private company. Registered by T. Rimington & Co., 43 Gallowtree Gate, Leicester.

FRANCO-BRITISH ELECTRICAL CO.—Registered on Oct. 12th, with a capital of £1,500, to acquire the business carried on at 99A Charing Cross Road, W.C., as the Franco-British Electrical Co., and to carry on the business of gas, electrical and general engineers, illuminating decorators, and contractors, &c. Private company Registered by W. B. Styer, 11 and 12 Fenchurch Street, E.C.

John E. Raworth,
Queen Anne's Chambers, 30, Broadway, Westminster, London, S.W.
Chartered Patent Agent.

THE 'PATENTEES' HANDBOOK,'
By J. G. LORRAIN, M.Inst.E.E. M.Inst.M.E.,
Chartered Patent Agent.
Gives full information and advice to intending Patentees. Sent Post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk Street, Strand, London, W.C.

SUMMARY

An article by Mr. C. F. Upward considers the advantages of enamelled wire over other forms of insulation, and gives useful data of space factors, &c., relating to its employment. (Page 959.)

The action by the General Electric Co. against the Welsbach Incandescent Gas Light Co., for applying a false trade description to the metal filament lamps which they have recently put upon the market, was continued at the Clerkenwell Police Court on Saturday. Mr. J. Y. Fletcher, the manager of the electric light department of the General Electric Co., gave evidence in which he contended that the use of the word "Aur" upon the lamps of the Welsbach Co. must create an impression in the mind of the trade that the lamps were either invented or made by Baron Welsbach, or that they were the product of the German Auer Co. Mr. A. J. Walter, K.C., cross-examined Mr. Fletcher at considerable length, and endeavoured to show that the German Auer Co. had not been known under that name in this country for two years. Mr. Fletcher admitted that the General Electric Co. had never used the word "Auer" in any trade advertisement of Osram lamps, and that these were known only as "Osram" in the trade. The hearing was adjourned for a fortnight. (Page 960.)

In a Paper read last week before the Manchester Section of the Institution of Electrical Engineers, Mr. J. W. Warr gave a description of the most usual forms of high- and low-tension electric ignition systems, both with battery and coils, and with magnetos, confining his remarks chiefly to the arrangements employed on automobile petrol engines. A number of interesting points were raised in the discussion. (Page 961.)

Some particulars of the electrical equipment of H.M. dockyard, &c., at Portsmouth, will be found on page 963.)

A slight interruption of the supply in the western district of Brighton occurred on Sunday night. The wash of a steamer passing the Southwick generating station partially stopped the flow of circulating water to the condensers, and caused one turbine to loose its vacuum. The discharge of steam through the air pump caused moisture to condense on an insulator, and this resulted in heavy arcing. An instrument transformer on one of the feeders burnt out, and earthed one phase, and although the feeder was automatically cut out, the pressure fell to such a degree that two motor-generators fell out of step at the North Road sub-station. (Page 963.)

The Highways Committee of the London County Council recommend that certain tramways in the neighbourhood of Greenwich Observatory be constructed upon the overhead system, using two trolley wires for each track. (Page 963.)

Digitized by Google

A PORTABLE electric saw is described on page 964.

UNDER "Electrometallurgy and Electrochemistry," a description is given of the Pauling process of extraction of nitrogen from the air by the electric arc, which is in use on a large scale at Innsbruck. (Page 964.)

SOME figures of steam consumption are given of a new 500 kw. turbo-generator recently installed at Tunbridge Wells. (Page 964.)

SPEAKING at the annual dinner of the Institute of Marine Engineers, last week, Mr. W. M. Mordey referred to the growing applications of electricity on board ship, and particularly to the recent methods of electrical propulsion proposed. (Page 965.)

THE Dover Corporation are advised not to investigate the S.P. surface contact system further until it has emerged from the experimental stage.—The Darlington Corporation have decided to join in the promotion of a Bill for securing municipal electric wiring powers, but the Gillingham Corporation have asked for further information on the matter.—A through tramway service has been arranged between the L.C.C., East Ham, West Ham, and Leyton systems.—Experiments are being carried out by the L.C.C. with a special brake for use on Highgate Hill.—Objection was taken at a meeting of the Morecambe Corporation to a proposal to appoint a borough electrical engineer at £150 per annum, several councillors protesting that this was inadequate. (Page 966.)

EXTENSIONS of plant are contemplated at Belfast, Burton-on-Trent, Birkdale, Rhyl, and Doncaster.—Electrical schemes are being prepared for the Amble and Newcastle (Ireland) Councils.—An electrical installation is to be installed at Whitchurch.—Electrical stores are required by the North-Eastern Railway Co., Dublin United Tramways Co., Wakefield and District Light Railways Co., and the Port of London Authority. (Page 966.)

A DIVIDEND of 50 per cent. is to be paid on the ordinary shares of the Deutsche Gasglühlicht Aktien-Gesellschaft (Auergesellschaft).—The A.E.G. of Berlin announce a dividend of 13 per cent.—At the annual meeting of the Edison and Swan United Electric Light Co. it was stated that the decreased profits were due to the decline in price of carbon filament lamps. (Page 968.)

A REVIEW of "Modern Electric Practice" is given on page 969.

ON Thursday last the action brought against S. M. Bodie to recover £1,000 paid as premium was concluded. On the Wednesday, Bodie gave a demonstration before the jury and an independent electrical expert to prove that he could withstand a heavy shock from a 12 in. spark coil, but the expert underwent the same treatment, and explained in court that there was no risk to life. In giving evidence, Bodie described the working of his other "electrical" effects. The jury returned a verdict against the defendant. (Page 970.)

THE inaugural address of Mr. R. K. Morcom as chairman of the Birmingham Local Section of the Institution of Electrical Engineers, delivered on Wednesday of last week, was devoted to a general review of the vicissitudes of the heavier branches of the electrical engineering industry during recent years. (Page 971.)

THE city of Boston has entered into a five-year contract with the local electricity supply company for street lighting. A gas company made strenuous efforts to obtain the contract, but the results of a number of comparative tests in streets illuminated with flame arc lamps, tungsten lamps, inverted Graetzin gas mantle and ordinary Welsbach mantle lamps, led the city authorities to adopt electric lighting. An interesting feature is the establishment of the 6·6 amp. magnetite arc lamp in the principal streets. We give particulars of the tests and comparative figures of costs. (Page 972.)

AN interesting Paper on high-tension switchgear by Mr. A. G. Collis was discussed last Saturday by the Glasgow Technical College Scientific Society. The author advocated ironclad gear for most purposes, and remote solenoid control for heavy feeder boards; he emphasised the necessity for complete provision for isolation, and described up-to-date forms of oil switches, instruments, and relays, discussing the most suitable arrangement of connections for the latter. (Page 973.)

AMONG the specifications published by the Patent Office on Thursday last was one by the Felten & Guilleaume-Lahmeyerwerke Akt.-Ges. for a method of insulating coils and armatures wound with bare wire by immersing them in a rubber or other solution and then vulcanising. A limit-switch for installations supplied on the contract demand basis, operating on the principle of a thermal "flasher" is protected by G. Wilkinson, and W. Stansfield and J. Hatt cover a method of compensating the speed variation of shunt motors due to heating of the field coils. A marine steering gear with a continuously running flywheel motor transmitting power to the rudder through solenoid-controlled friction clutches is described by B. Parker-Haigh, and an improved pattern of automatic battery charging switch by Nalder Bros. & Thompson, Ltd. A. West protects a motor controller in which the drum is made up of a series of discs with spring knife switches to obviate the necessity for a magnetic blow-out. Among the expiring patents is one by G. Flett and Dick, Kerr & Co., for a rail joint, and two by W. R. Sykes and E. Tyer respectively for railway signalling apparatus. A patent covering the use of closed circuit coils, and an adjustable shunt inductance in motor induction meters, taken out by G. Hummel, also expires during the current week. (Page 974.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, NOVEMBER 11TH.

Institution of Electrical Engineers.

8 p.m. Presidential Address by Dr. Gisbert Kapp.

Institution of Electrical Engineers: Dublin Section.

8 p.m. At the Royal College of Science. Chairman's Address.

FRIDAY, NOVEMBER 12TH.

Northampton Institute Engineering Society.

5.45 p.m. At the Institute. "Application of the Steam Turbine to Marine Propulsion," by Mr. Dicksee.

Institution of Electrical Engineers: Birmingham Section.

7 for 7.15 p.m. Annual Dinner at the Grand Hotel.

SATURDAY, NOVEMBER 13TH.

Birmingham and District Electric Club.

7 p.m. At the Colonnade Hotel. "A Discussion on Problems of Power Generation and the Transmission and Distribution of Electrical Energy," by Carl de Hoedt.

MONDAY, NOVEMBER 15TH.

Electro Harmonic Society.

8 p.m. Concert (Ladies' Night) at the Holborn Restaurant.

Institution of Electrical Engineers: Newcastle Section.

8 p.m. Meeting at the Armstrong College of Science.

TUESDAY, NOVEMBER 16TH.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. Meeting at the University. Paper to be read:—"Telephones," by L. E. Wilson.

Institution of Electrical Engineers: Glasgow Section.

8 p.m. Meeting at 207 Bath Street. Mr. E. G. Tidd, the Chairman, will deliver his Address.

Institution of Civil Engineers.

8 p.m. Further discussion on electrical engineering Papers read last week.

WEDNESDAY, NOVEMBER 17TH.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. Meeting at 92 Victoria Street, London, when Mr. J. H. Rider will deliver an Address on "The Importance of Attention to Details."

Institution of Electrical Engineers: Leeds Section.

7.15 p.m. At the Sheffield University. "Some Experiments on Single and Stranded Fuses," by T. T. Maccall.

Royal Society of Arts.

8 p.m. Address by Sir William H. White, K.C.B., F.R.S.

Digitized by Google

ENAMELLED WIRE

By C. F. Upward

ONE of the most important points in connection with the manufacture of insulated copper wires, so far as they are employed for the windings of electrical machinery and apparatus, lies in the reduction of the thickness of the insulating material to the lowest limits compatible with mechanical strength and efficient insulation, in order to utilise the winding space available to the best advantage.

For many years silk and cotton have been used almost exclusively as insulating materials. Owing to the nature of these materials, however, they easily absorb moisture, and it is necessary in most cases to impregnate them with some substance which renders them moisture proof. Further, in special instances two or even three layers of material must be used in order to ensure perfect insulation, and on account of the spinning process employed it is not possible to use threads of less than a certain thickness. It will, therefore, be readily understood that a considerable space which might be advantageously used for additional copper is taken up by the insulating material in coils wound with cotton or silk insulating wire.

From the foregoing it is clear that any improvements in the insulation would have to be sought for in an entirely new direction, and as the results of this conclusion a new type of insulated wire has been produced, which goes by the name of enamelled wire. This name was introduced by the Allgemeine Elektricitäts Gesellschaft, who were the first firm to take up the commercial manufacture of the wire. Enamelled wire is so called owing to the characteristic nature of the insulating material, which is similar in appearance; it differs from this substance, however, in the fact that it possesses a high flexibility.

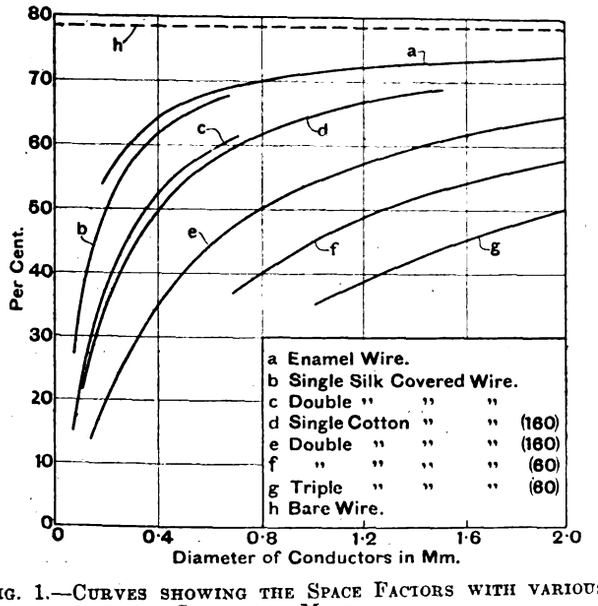

FIG. 1.—CURVES SHOWING THE SPACE FACTORS WITH VARIOUS INSULATING MATERIALS.

The principal feature of the new wire is the thinness of the insulation, owing to which it is highly suitable for the winding of coils. The accompanying Fig. 1 gives a series of curves showing the space factors for enamelled wire, single and double silk-covered wire, also single and double cotton-covered wire, cottons Nos. 50, 160 and 200 being used for the latter. A table is also appended, in which the comparative figures for the respective materials are given. It will be seen that enamelled wire up to a diameter of approximately 0·6 mm. has a better space factor than even single silk-covered wire, and that it is considerably higher than all cotton-covered wires, including those insulated with the finest cotton, No. 200.

Table giving the Space Factors for Different Insulating Materials, in Per Cent.

Diam. of wire, mm.	Enamel wire.	Silk-covered wire.		Cotton-covered wire.			
		single.	double.	160 single.	160 double.	60 double.	60 triple.

In order to demonstrate further the economy in space which may be effected by using enamelled wire, two coils are shown side by side. In the winding space of the first coil, Fig. 2, 3,000 turns of enamelled wire, having a copper diameter of 0·5 mm., are wound,

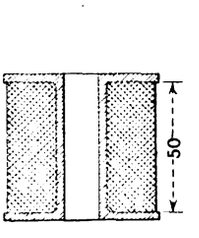

FIG. 2.

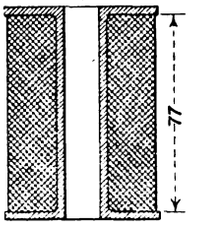

FIG. 3.

whereas only 2,560 turns of wire of the same thickness double silk covered or single cotton covered (No. 160) can be wound on a coil of the same size, or only 1,940 turns if a double cotton-covered insulation (No. 160), or single cotton covered (No. 150) are employed. Fig. 3 gives the dimensions of the coil which would be necessary in order to have the same number of turns of double cotton-covered wire (No. 160) as those on the smaller coil wound with enamelled wire. The above figures are still more in favour of enamelled wire when the fact is taken into account that the latter has a much higher loading capacity than wires covered with other insulating material. Owing to the methods of manufacture employed the wire is capable of withstanding very high temperatures, and coils wound with enamelled wire may be safely used up to temperatures of 150° C. continuously, or 200° C. temporarily. It is not possible to state the value of the maximum current which is permissible without the given temperatures being exceeded, as the temperature of the

Digitized by Google

coils will be largely dependent upon the cooling conditions prevailing. According to tests carried out, however, it has been found that under normal conditions, with the coils loaded continuously, the Watt consumption (continuous current) must be equal to two-thirds of the product of the height of the coil (in cm.) and its diameter (also in cm.),

$$\text{or: } W = 2/3 \text{ hd.}$$

For intermittent loading no single formula can be given, as it is necessary to take into account the length of time during which the current is flowing, in addition to the Watt consumption.

Another advantageous quality of the enamelled insulation is the high degree of flexibility and toughness which it possesses; a short length of the wire may be wound round another piece three times its own diameter, in close coils, and subsequently unwound again without the insulation cracking or being affected in any way. The layer of insulating material is from 0·01 mm. to 0·03 mm. thick, according to the diameter of the wire. Notwithstanding its thinness, however, this covering has a great disruptive strength, a voltage of 2,500 to 3,000 volts being necessary to pierce the insulation of two wires, each 1·2 diameter, stranded together and in a dry condition. The insulation voltage of single wires in contact with the mercury is from 2,000 to 2,500 volts, or with water 800 to 1,000 volts after 24 hours' immersion.

Enamel insulation is entirely non-hygroscopic. Acids only attack the wire at high temperatures; the enamel compound, on the other hand, has no great resistance to alkalies, and should not be allowed to come into contact with any alkali liquids. Among the organic chemicals only benzine, benzol, alcohol and acetone affect the wire when warm, whereas turpentine and chloroform attack it when cold. Enamelled wire may be used for winding field coils, inductor coils, &c.; it is also largely employed in place of cotton-covered wires for arc-lamp coils, dynamo exciter windings, and other similar purposes.

THE WELSBACH METAL FILAMENT LAMP: ACTION BY GENERAL ELECTRIC CO.

IN the Clerkenwell Police Court on Saturday, Mr. Bros sat for the third time to hear the summonses taken out by the Wolfram (Tungsten) Metal Filament Lamps, Ltd., and the General Electric Co., Ltd., against the Welsbach Incandescent Gas Light Co., Ltd., for applying a false trade description to the metal filament lamps which they have recently put upon the market. Mr. Rufus Isaacs, K.C., M.P., Mr. H. A. Coletax, and Mr. E. Lunge are appearing for the prosecutors, and Mr. A. J. Walter, K.C., and Mr. A. H. Bodkin for the Welsbach Co.

Mr. J. Y. Fletcher, the manager of the electric light department of the General Electric Co., said that it was in November and December, 1906, that Osram lamps were first sent to the country by the Auer Co., and although these lamps were now manufactured in England, owing to provisions of the new Patent Act, a certain number were still imported from Germany. The lamps, when first imported into this country, bore the words "Auer Gesellschaft," but this was discontinued at the end of the first three months. With regard to the advertisement in the *Daily Telegraph*, which asked purchasers to see that the words "Welsbach Aur" were upon the lamps, he stated that the German Welsbach Co. was known here as the Auer Co., and that in his opinion these words on the lamp, together with the words "made in Germany" on the cap of the lamp, must create the impression in the trade that the lamps were either invented by Baron Von Welsbach, or made by him, or that they were made by the German Auer Co. As a matter of fact, this was not so, and he was not aware of any lamp invented or made by Baron Von Welsbach which bore the word "Aur." The General Electric Co. advertised Osmium lamps as the invention of Baron Von Welsbach until the use of tungsten as a filament was discovered. Thirteen of the lamps purchased by the General Electric Co. had been handed to Dr. Oberlander, and the remainder were still in the possession of the General Electric Co.

In cross-examination by Mr. A. J. Walter, K.C., Mr. Fletcher admitted that he had not the permission of Mr. Holloway to use his card as had been done in order to purchase the lamps from the Welsbach Co., but such a person did exist. He had adopted this method in order to ascertain what the Welsbach Co. told their customers when selling these lamps.

Dealing with the assertion of the General Electric Co. that the German Welsbach Co. is commonly known in this country as the Auer Co., Mr. Walter produced an Osmium lamp, and pointed out that the only words upon that were "Patent Osmi." Mr. Fletcher said he was not aware that the German company had intended to call the lamp "Auroslamp" or "Auerosmi," and that they had endeavoured to register either or both of these words in this country. Neither was he aware that the Austrian Welsbach Co., at the instigation of the English Welsbach Co., had objected to this, and that the German company, in consequence, undertook not to use the words "Auer" in any way in this country. Mr. Fletcher admitted that he was aware of an undertaking of this character with regard to gas mantles for a certain period which had now expired, but he had made no inquiry from the German company as to their position in this matter with regard to electric lamps. He was not aware, he said, that the German company had written a letter on December 17th, 1904, in which they agreed to omit all reference to the word "Auer" in their title in England. It was also put to Mr. Fletcher that the German company was now commonly known in his country as the "DGA," and Mr. Walter produced a sheet of the firm's letter paper, on which these letters appear in the form of a monogram. Mr. Fletcher said his firm had not had any correspondence from the German company on such letter paper, but he had heard the company referred to in that manner. He was not aware, he said, that the word "Dagea" was the registered trade mark in this country of the German company for electric lamps, and, in reply to a question that the German company had omitted all reference to the word "Auer" in their title for two years, Mr. Fletcher said the company had been commonly known to him here as the Auer Co. for the last two and a half years. During that period, however, it was true that no advertisement of the German company had appeared here containing the word "Auer." He was not aware that an agreement dated October 23rd, 1907, between the Wolfram (Tungsten) Metal Filament Lamps, Ltd., and the German company in regard to the use by the former of patents by Just & Hanaman, referred to the German company as the "DGA." The General Electric Co. has taken over the German company's trade mark of "Osram" for this lamp, and it was quite true that no trade advertisements had been issued by the General Electric Co. of Osram lamps in which Baron Von Welsbach's name appeared as the inventor or maker, nor had they ever used the word "Aur" in connection with Osram lamps. The word "Osram" was registered in Class 13 as the trade mark of Osram lamps, but he was not aware that since January 17th, 1909, the word "Aur" had been registered by the Welsbach Co., in the same section, also for electric lamps. But although this word had been used on gas mantles, &c., by the Welsbach Co., Mr. Fletcher contended that it was not commonly used on electric lamps, and, indeed, to his knowledge, had never been used until recently, when the Welsbach Co.'s advertisement first appeared. With regard to the use of the words "Welsbach" and "Auer," in connection with metal filament lamps, Mr. Fletcher referred to a reprint of an article which appeared in the *Standard* and the *Daily Telegraph* in August, 1907, in which Baron Von Welsbach was referred to as the inventor of the first successful commercial electric lamp, but beyond this he could not say that the Baron's name had been used by the General Electric Co. in connection with electric lamps. Mr. Walter immediately put it to witness that in this article the General Electric Co. used Baron Von Welsbach's name in connection with a lamp which he had not invented in precisely the same way that they were now complaining that the Welsbach Co. had done. Mr. Fletcher replied that in the article in question it was stated that Baron Von Welsbach invented the Osmium lamp, and the Osram lamp was a develop- of this. It was quite true that Osmium lamps had not been made for high-voltage circuits. He was quite prepared to admit that "Osram" was the only name by which Osram lamps were known on the market in this country.

He was not aware that Baron Von Welsbach was still the registered legal owner of the original Osmium Patent, No. 1,535 of 1898, nor that two other Osmium patents taken out by Baron Von Welsbach, namely, Nos. 13,116 and 17,580 of 1898, had lapsed. Neither the German company nor the General Electric Co. owned any of the English patents of Baron Von Welsbach's. He believed, however, that the Wolfram Co. owned some of the English Welsbach patents.

In re-examination by Mr. Rufus Isaacs, K.C., Mr. Fletcher said that the advertisement in the *Daily Telegraph* was the first intimation he had that the Welsbach Co. intended to sell electrical goods. It was quite a new departure on their part. With regard to the point made by Mr. Walter that the original Osmium lamps did not bear any reference to the Auer Gesellschaft, Mr. Fletcher produced the wrapper of one of these lamps, upon which he pointed to several references to this name, and these lamps had been sold in similar wrappers in this country for two years and three months.

The hearing was adjourned for a fortnight.

ELECTRIC IGNITION

At the meeting of the Manchester Section of the Institution of Electrical Engineers on Tuesday of last week a Paper was read by Mr. J. W. Warr on the "Electric Ignition of Internal Combustion Engines." Dealing first with low-tension systems, in which the spark is produced by breaking an inductive circuit, after discussing the early arrangements with batteries and series inductance coils, he described a typical form of tappet gear for effecting the necessary break inside the cylinder. The contacts, one of which is a fixed insulated plug, while the other is carried on an uninsulated radial arm, are allowed to come together just before the moment of ignition, and then sharply separated by the action on a cam. A simple method of retarding and advancing the ignition by altering the position of the follower relatively to the cam was described, but it was mentioned that with low-tension ignition, some car builders permanently fix the period of firing with no adjustment to suit high or low speeds.

In order to dispense with complicated mechanical striking

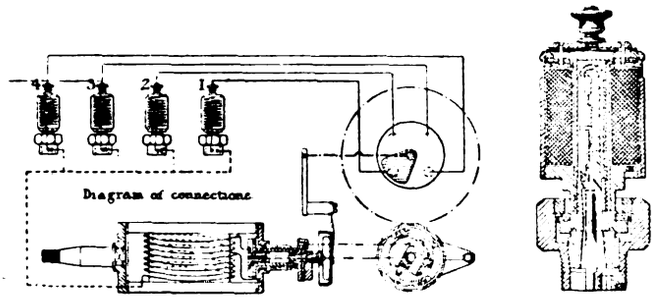

FIG. 1.—LOW-TENSION MAGNETO SYSTEM WITH MAGNETIC PLUGS.

gear and tappets, magnetic plugs or electrical tappets are sometimes used. A diagram of connections and a section of the plug are shown in Fig. 1. The current is generated in the two windings of the revolving armature from the permanent field, and attains a maximum voltage twice during each revolution. The armature is driven at crank-shaft speed. In the diagram of connections the dotted lines represent the completed circuit by the car frame. On the right-hand side of the armature is shown the contact-breaker through which the auxiliary winding is periodically short-circuited just previous to the current attaining its maximum. When the spark is required the contact-breaker opens and a current impulse flows through the coil of

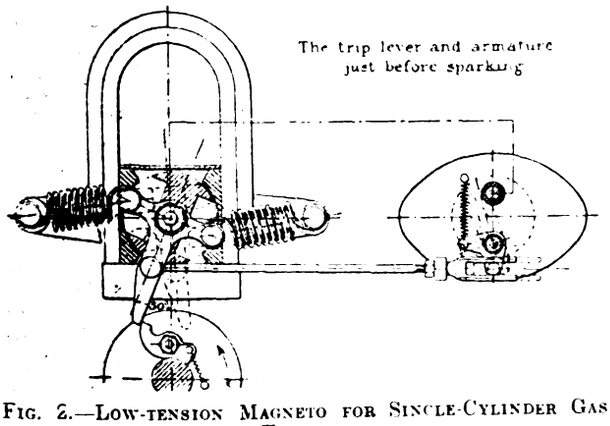

FIG. 2.—LOW-TENSION MAGNETO FOR SINGLE-CYLINDER GAS ENGINES.

the magnetic plug by way of the distributor, vigorously attracting the armature interrupter of the plug and effecting a quick breaking of the contacts. This produces a powerful spark in the same way as the mechanical tappets. The variation in timing is effected by rotating the lever embracing the make and break contacts shown on the right-hand side of the drawing, directly below the distributor. (Some further details of these plugs were given in ELECTRICAL ENGINEERING, Vol. III., p. 798.)

A form of low-tension magneto igniter that is used chiefly with single-cylinder gas engines is shown in Fig. 2. The current is produced by an oscillating motion of the armature, and is moved out of its position of rest through an angle of 30°, a thumb on the cam shaft striking the trip lever on the armature shaft. The horizontal springs bring the armature into its normal position. The tappets break circuit when the armature has passed a few degrees beyond its normal position. The variation of ignition is obtained from a device on the cam shaft, so that the releasing of the trip lever takes place early or late as required.

The main objections to low-tension ignition are: wear of the tappet points and the moving parts within the combustion chamber, wear and tear of striking gear whilst operating at high speeds and constant need of adjustment, which in many cases can only be perfectly carried out by experts.

In speaking of high-tension ignition with batteries, the author said that in looking after accumulators too much reliance was usually placed on the voltmeter reading after charging, and unless the cell was doing service on its own coil or a suitably closed circuit, a fictitious reading was likely to be the result due to recuperation characteristics. Again, it was advisable to take readings of each individual cell, and make observations of the colour and condition of the plates, looking out for internal short-circuits due to disintegrated active material at the bottom of the cell. Dry cells could also be used for this purpose, and their life was lengthened by the use of several connected in multiple series.

In induction coils it was of the utmost importance for the capacity of the condenser to be correctly proportioned. The best results were obtained when the self-induction of the primary and the capacity of the condenser were balanced, producing resonance. The larger the current passed through the primary (which can be produced by overscrewing the contacts) the greater should be the capacity of the condenser. On the other hand, the gradual burning away of the platinum reduces the current in the primary and produces unbalanced effects with the condenser. The author recommended the use of a moving-coil ammeter in the primary circuit when adjusting tremblers, and

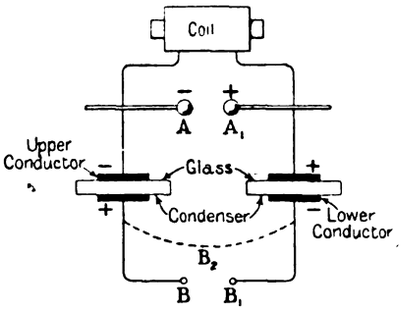

FIG. 3.—DIAGRAM OF LODGE SYSTEM.

remarked that a very light fuse would be a useful addition in the event of the contact screw being lowered too far. After being in use for some time the platinum appears to leave the positive contact and builds up on the negative. A reversing switch can be used to keep the contacts level and do away with the filing of an expensive metal. Of faults with ignition coils, internally punctured insulation make up a large percentage. The author is of opinion that a permanently fixed spark-gap would prevent a number of troubles, as the coil is often operated with the secondary on open circuit by inexperienced persons when endeavouring to locate the causes of misfiring. In any type of coil it is of the utmost importance to have an iron wire core that will admit of rapid changes of the magnetic flux.

The ordinary methods of distribution with separate trembler coils to each cylinder, and a multiple-way primary contact-maker, and with a single-coil and high-tension distributor, were described, and the general principle of the Lodge coil was outlined (see Fig. 3). The high-tension circuit is connected to the plugs through the intervention of two condensers with their outer coatings connected through a leakage path or imperfect conductor, the object of which is to keep them always at the same potential, except at the instant of sudden discharge. No strain is thrown on the plug leads, they remaining at the same potential up to the last moment when the two condensers are full and overflow at *A*. At this instant everything is liberated, and with great rapidity the condensers empty themselves across *A* and round the completed circuit to the sparking plugs. The high-frequency discharge is so violent that soot round the plug electrodes is flung away, also the spark will blaze through water. A trembler coil furnishes the high-tension current for the condensers, and the secondary winding of the coil is built up in sections. The coil only takes 0·75 of an ampere for a four-

Digitized by Google

cylinder engine, which is only a very small figure compared with other coils. Only one coil is used, the high-tension current being conducted to the cylinders by a high-tension distributor working on the cam shaft. Two tremblers are provided which work at each end of the iron core, but only one is in operation at a time, a single pole throw-over switch putting either one or the other in circuit. A reversing switch is also fitted so as to enable the platinum points to wear evenly.

A system of ignition with a magneto and ordinary trembler coils was then described, and also an arrangement with a single plain coil and high-tension distributor.

Probably the most popular form of ignition, continued the author, is the one in which the high-tension current is produced in the armature of the magneto. This system is the simplest when compared with what has already been described. The diagram of connections in Fig. 4 represents a high-tension mag-

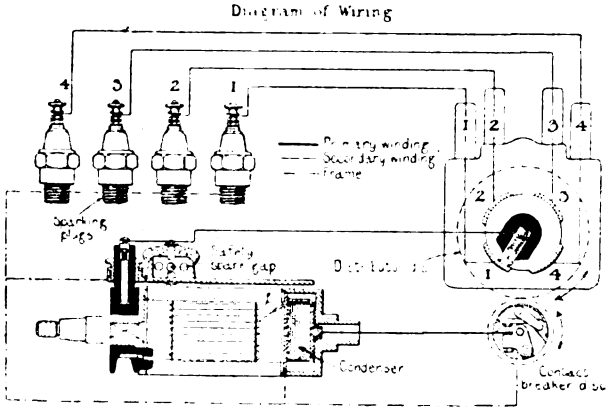

FIG. 4.—HIGH-TENSION MAGNETO SYSTEM.

neto for a four-cylinder engine. Between the pole-shoes of the permanent magnets rotates a shuttle-wound armature on which are two windings, a primary and a secondary, the latter forming a direct continuation of the primary. The alternating current generated in the primary winding attains its maximum twice during one revolution, the two maxima being 180° apart. The high-tension current is produced in the secondary by short-circuiting and opening the primary circuit through the platinum pointed contact-breaker twice in each revolution. At the moment the circuit is broken the high-tension current is collected from the slip-ring by a carbon brush and taken to the distributor and plugs by the contact brush driven from the armature spindle. The armature is driven at crank-shaft speed, so that when the winding is cutting maximum field its position must correspond to a definite position of the piston.

Another type of high-tension magneto (Fig. 5) is one in which

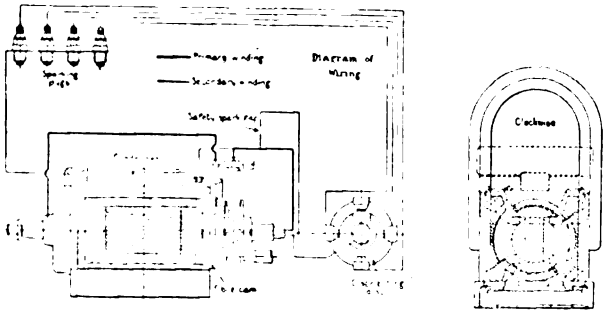

FIG. 5.—HIGH-TENSION MAGNETO SYSTEM WITH INDUCTOR MAGNETS.

the generation is based on the same principle as the well-known inductor alternator. The armature winding is stationary and mounted in the permanent field. A tubular soft iron inductor envelope having two slots cut in it, each representing a quarter of its circumference, revolves between the armature and the pole-shoes. By this means the current in the primary will attain its maximum when the inductor has rotated through an agle of 90° or four times per revolution. By rupturing the primary circuit during the effective periods a current is induced in the secondary winding four times per revolution. As no slip-ring or collector is required, the high-tension current is conducted straight to the brush contact of the distributor disc.

With all these systems, dual, or even triple, ignition can be fitted, and an arrangement has been brought out recently for using the high-tension magneto armature as a coil for starting by means of a dry battery, but the author was of opinion that energising the armature in this way will in time reduce the field strength of the permanent magnets.

DISCUSSION.

Mr. J. G. WALTHEW, in opening the discussion, said that it seemed to him that for motor-cars, the low-tension system was preferable to the high-tension system, but for stationary multi-cylinder gas-engines, the high-tension system was the best on account of its freedom from wear and tear. He thought, however, that the low-tension system was all that could be desired for a single-cylinder gas-engine. Complaints of excessive wear on the tappets and sparking points were generally found to be due to bad setting of the contact breaker.

Mr. J. FRITH had used dry batteries to replace accumulators, with success, but could not recommend putting them in series parallel, as they tended to gradually run down, due to small differences in the E.M.F.'s of the cells in parallel. He did not think that many motorists would willingly consent to a fuse in the battery circuit of their cars. It was a pity that the author did not distinguish between those magnetos which always used the most effective position of the armature for producing the spark, and those in which the retarding and advancing of the firing point was done at the expense of not using the crest of the E.M.F. wave in each case. The question of simultaneously firing the charge at more than one point in the cylinder by means of two plugs in series, worked from the same coil, or magneto, was engaging the attention of motorists just now. He also called attention to the necessity for a separate earth to contact maker, other than that through the film of oil in the bearing.

Mr. R. B. SLACKE (Key Engineering Co.), after a few remarks on motor-car ignition, described a system for large gas-engine work where the voltage was from 60 to 100; a mechanical cast-iron tappet was actuated by a solenoid, and there were slip-rings on the cam shaft, which closed the circuit round the solenoid and the tappet, so that the effect of the solenoid was to open the tappet and let it shut again, thus getting the spark. There was a brush rocker for altering the timing, but this was not used on account of variations of the speed of the engine, as in motor-car work, but was advanced or retarded as the mixture was weak or rich. One or two Continental firms had had experience with Lodge ignition, and in at least one case this had now been adopted in preference to the other.

Mr. H. MILNE ATKINSON had lately had the opportunity of examining some low-tension plugs which had just been withdrawn from the cylinders of a large gas-engine. One of the chief faults was that the two surfaces of the fixed pin and moving lever did not always exactly coincide. One was apt to overlap the other, and thus a ridge was worn, and uneven firing was set up.

Mr. K. Cox (Westinghouse Co.) said that wipe contacts were fairly satisfactory, but with the make and break contacts the brushes burned very badly, and had to be replaced very often. If the wipe contact was made of a suitable material, there would be very little trouble experienced with it. He thought it was certainly an advantage to have a gap on the outside, especially in multiple cylinder engines. It gave a chance of actually seeing if there was a plug mis-firing, due to any external cause.

Mr. R. COWELL remarked that his experience with cars had been that very much more power could be obtained with magneto ignition than with a battery.

Mr. A. R. STELLING, in comparing oscillating and rotating shuttles in magnetos, said that he was in favour of the oscillating shuttle, combined with an inductor envelope. There was then a very small moving mass, and very slight mechanical reaction, whereas with an ordinary-wound shuttle oscillating, unnecessary vibrations were liable to be produced, and further, the wires were very apt to either break down as to insulation, or break loose altogether. Another advantage was that very accurate timing was possible with the oscillating type. Again, one was apt with the rotating type to be compelled to make use of an undesirable portion of the E.M.F. wave, whereas with the oscillating type and by adjusting the tappet one was always able to take the current at the top of the wave; also with the rotating shuttle the E.M.F. varied with engine speed, so that they could not be used for starting up.

Mr. H. J. COATES remarked that in magneto-ignition systems it appeared to be now the standard practice to place the high-tension winding over the armature winding. Whilst this construction lent itself to extreme compactness, it was open to doubt if this really was the best place, as the difficulties of sound insulation were often considerable, in spite of the limitation of the voltage rise due to the provision of a protective spark-gap. In some few makes the transforming element was placed over the armature box underneath the arch of the magnets. This disposition appeared to be a better one for providing effective insulation, and reducing the risk of breakdown. With coil ignition he recommended a single trembler, even with multiple coils.

After a few remarks from the Chairman (Mr. S. J. Watson), Mr. WARR, in reply, said that he should always prefer high-

Digitized by Google

tension ignition both for motor-cars and stationary engines. The methods of producing the low-tension current itself undoubtedly tended to simplicity, but its application in connection with striking and tappet gear must set up excessive wear and tear. He could hardly advise their use as to dry batteries for an ordinary make and break contact and plain coil, but with a trembler coil the cell was quickly exhausted. In reply to Mr. J. Frith, the application of the fuse was only required in the absence of a suitable ammeter for setting the trembler blade. The magneto was certainly more expensive in initial cost than the coil equipment, but as the mechanism was more simple and compact the chances of a breakdown were, in his opinion, reduced. There was no doubt that greater power was obtained from a magneto than from a coil as the speed of the armature increased; the spark produced became larger and hotter, and combustion was commenced and progressed more rapidly.

ELECTRICAL EQUIPMENT OF H.M. DOCKYARDS

A BRIEF note under the heading "Portsmouth" in our last issue, and inspired by one of our Service contemporaries, was not quite accurate. The electrical equipment of Portsmouth Dockyard is practically complete, as well as the dockyards at the other naval ports at home and abroad. The workshops at Portsmouth Dockyard, with only one or two exceptions, have been fully equipped with electric light and power.

This work was completed early this year, and was commenced a little over five years ago, and the change over from steam power to electric driving was effected without stopping work in any of the shops for a single day.

The dockyard is supplied from its own electric power station, with a capacity of about 5,000 kw. The Naval Barracks and Whale Island are supplied by special feeders from this power station; but on the other hand, Haslar Hospital, Fort Blockhouse Submarine Depot, and the Ordnance Depot at Priddy's Hard have their own supply stations, whilst Eastney Barracks and the Naval Guardship, also electrically lighted, are supplied from the Portsmouth Corporation's electric power station.

All this work has been carried out under the direction of Messrs. Preece & Cardew, the consulting engineers to the Admiralty, for whom Mr. William H. U. Marshall acted as resident engineer at Portsmouth.

INTERRUPTION OF SUPPLY AT BRIGHTON

ON Sunday evening last the electricity supply in the western district of Brighton was interrupted for a few minutes, due to a slight mishap at the Southwick generating station. The primary cause of the trouble was a coal steamer coming alongside in the dark on a very low neap tide. The scour of the propeller stirred up the mud to such an extent that it partially stopped the flow of circulating water to the condensers. One of the turbines lost its vacuum and went to atmosphere, causing a heavy discharge of steamy vapour through the air-pump into the basement adjacent to the high-tension switchgear. The moisture condensed on the cold surface of the porcelain insulators, and heavy sparking took place. An instrument transformer on one phase of one of the feeders burnt out and short-circuited that phase to earth. Fortunately, the corresponding automatic overload relay tripped all right and cut the feeder out; but, as it was set with a very heavy overload and a five-second time-limit, the primary voltage fell away to such an extent that the motor-transforming plant at the North Road sub-station slowed down.

At Southwick everything was normal in a very few seconds, but at North Road sub-station, where the H.-T. supply is transformed to continuous current to supply the tramway system at 550 volts, the outer lighting area at 460 and 230 volts, and the central area at 230 and 115 volts, there was some trouble. The tramway system and the central area only had low voltage for about thirty seconds, but in the case of the 460-volt supply, which was being run at the time by four 500-kw. induction motor-generator sets, the effect was more serious. When the H.-T. voltage dropped, two of the sets cut themselves out from excess current on the H.-T. side, and although the voltage was never off the system, it was very seriously reduced, and it was some three or four minutes before the machines could be paralleled again and the supply restored to its normal condition.

GREENWICH OBSERVATORY AND ELECTRIC TRAMWAYS

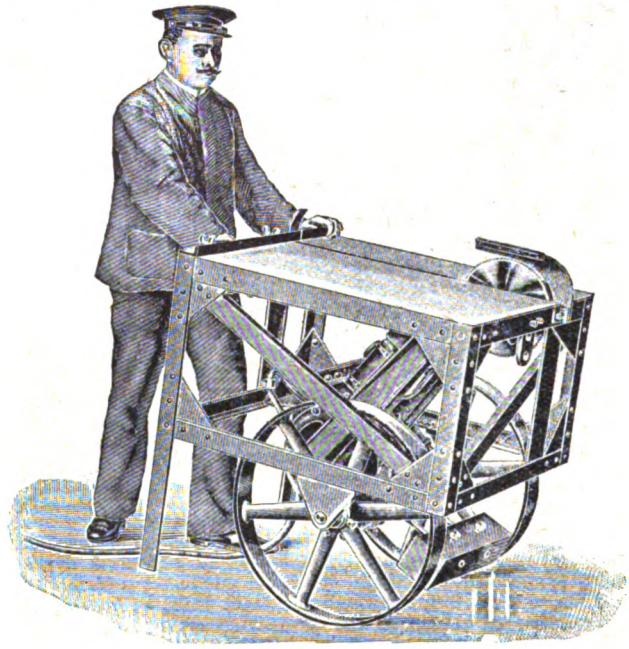
A SHORT time ago we announced that the Astronomer Royal had objected to the construction of electric tramways from Woolwich to Eltham on either the conduit or overhead system owing to danger of electrical interference with the Observatory instruments. The Highways Committee of the London County Council have now reported upon the matter. The Woolwich Borough Council has completed widenings at a very considerable cost, and the Committee feel very strongly that there should be no further delay in undertaking the construction of the tramways. The reason for the delay in proceeding with the line has, it is said, been due largely to the unsatisfactory financial results anticipated from the working of the tramways, and they have for some time been considering the question of minimising this loss by adopting a less expensive system of traction than the underground conduit system. With this object they have been in negotiation with the Board of Trade and the Admiralty with a view to the construction of the lines on the overhead trolley system of electric traction. The Admiralty has, however, declined to agree to the adoption of the usual overhead trolley system with a single insulated conductor overhead and with the return circuit through the track rails, or to the modification thereof known as the three-wire system, in which the currents in the return circuit are balanced. The grounds of the Admiralty's objection to these proposals are that so long as one of the conductors supplying energy to the tramways is uninsulated there is no known method whereby the risks of stray currents passing through the soil can be wholly eliminated, and it considers that the insulation of all conductors is essential in order to secure that the instruments at the Royal Observatory, Greenwich, may be entirely free from possible interference from the working of the tramways. The Committee are advised that complete insulation of all conductors on the overhead system can be obtained by using two overhead wires instead of one for each track as in ordinary cases of overhead electric tramways, and in the circumstances they have decided to recommend the Council to arrange for the construction of the lines in this manner. It will be desirable to terminate the insulated system of traction at a point some distance south of Beresford Square, and to arrange for the short length of the tramways between this point and Beresford Square to be constructed on the ordinary overhead system. This short length of line will be at a distance of more than three miles from the Royal Observatory, so that the adoption of the course suggested, which will simplify the overhead work and facilitate the reversing of the cars in Beresford Square, will not give rise to any difficulty as regards the work of the Observatory. The arrangements proposed will admit of running through cars between Eltham and Abbey Wood.

The estimates of the cost of the construction and equipment of the lines as suggested are as follows:—Trackwork, £37,920; rails, £8,650; special work, £1,430; overhead equipment, £10,500; cars, £7,600; cables, £4,250; ducts and duct-laying, £5,600; feeder pillars, £280; sub-station equipment, £250, making a total of £76,480.

The new tramways will consist of about 2 miles 3 furlongs 7 chains of double line, and about 1 mile 1 furlong 3 chains of single line, as on part of the route the lines are authorised in separate streets.

Birthday Honours.—Among the birthday honours we notice that Mr. W. J. Crossley, chairman of Messrs. Crossley Bros. & Co., Ltd., has had the honour of a baronetcy conferred upon him.

Wireless Telegraphy.—It is stated that a French company is in treaty for the purchase of the Bellini-Tosi wireless telegraph system.



A British Consular Report states that the station at Fort de l'Eau on Algiers Bay is open for commercial purposes. The cost of the message is collected on shore from the person receiving and appears somewhat high, as a message delivered recently worked out at about 10d. per word for some 200 miles.

According to the annual report of Lloyd's Register, there are now 404 merchant vessels equipped with wireless telegraph apparatus.

A PORTABLE ELECTRIC SAW

THE accompanying figure represents a portable self-contained electrically-driven circular saw equipment, which Messrs. Feld Bros. & Co. (25 Budge Row, E.C.) are placing on the market. The apparatus should have a considerable field of usefulness, as there are many cases where a large amount of labour can be saved by bringing the saw to the material instead of the material to the saw. The machine can be wheeled by one man, and only requires connecting up by a flexible cable

PORTABLE ELECTRIC SAW.

to be ready for use. The belt-driven saw is mounted on a swinging bracket, so that for cross-cutting the saw can be pulled through the work, while for longitudinal cuts the planks are pushed over the table in the usual way. The starter is carried on the machine. The size illustrated has a 2 to 3 h.p. motor, and can be supplied for voltages up to 240. The top is 31½ in. wide, and the depth of cut is 3 in. A heavy pattern is also made. The company also supply powerful saws of somewhat different design for cutting up felled trees, and another pattern for cutting logs, beams, &c.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

RECENTLY a good deal has been heard of the processes of Birkeland and Eyde and of the Badische Company, but it is not so well known that there is a third process in operation in Patsch, near Innsbruck, in the Tyrol. The power is obtained from the small river Sill. The works are owned by the Salpetersäure-Industrie-Gesellschaft in Gelsenkirchen, and the process has been invented by the brothers H. Pauling and G. Pauling. A paper on the subject was recently published in the *Oesterreichische Chemiker Zeitung*.

In the Pauling process arcs are produced between two curved electrodes, which are like the horn lightning arrestors. The arc is lighted from the bottom, where the horns are nearest together. The arcs rise upward owing to the rising of the heated air, and are broken by every half-period of the alternating current; a new arc is then lighted at the bottom, and so on continuously. By blowing an air current at high speed between the electrodes, the arc is still further lengthened, so that arcs of very considerable length can be obtained. In order that the very large volumes required in practice may be blown through the arc, the voltage required to maintain the arc over the minimum distance of the horn is considerable. A special method is also employed for striking the arc. At the lower end of each electrode a slit is cut, through which thin protruding blades are fixed, the distance between the two blades being easily adjusted by hand. The blades are very thin, and consequently do not interfere with the air current, so that it can enter with full effect into the arc.

The main electrodes are placed so that an air current of about 1·6 inch in width passes through the narrowest point. The air is pre-heated, the heating being performed by the heated gases as they leave the arc. A great advantage in employing these thin blades is that the main electrodes are fixed, and therefore the arc is easily regulated. The flame burns quietly, and appears on observation to be quite stable. In practice its length is about 39 in., although it is possible to produce longer flames. The electrodes are made of iron, are water-cooled, and have a life of about 200 hours. The blades have, as might be expected, a shorter life, but they are readily renewed.

In order to cool rapidly the escaping air after it has passed through the arc, cold air is passed through the upper part of the flame. It is supplied into the flame at a lower speed than the lower main air current. This causes a suction effect on the arc, and serves to both lengthen and broaden it out. It is claimed that on the large scale a concentration of nitrogen oxides of about 1·5 per cent. is obtained.

The furnaces are built of brick, and each contains two arcs. The capacity of the furnaces is 400 kw., with a voltage of 4,000. In an hour 600 cubic metres of air are passed through each furnace, exclusive of the cooling air. There are at present twenty-four furnaces in operation at Innsbruck. Very little labour is required to look after the furnaces, one man being able to attend to four furnaces.

In each furnace two arcs are used in series, and a very high resistance is inserted between the centre pole and one of the outer ones. Consequently the full voltage is first impressed on the opposite side, between the outer and centre pole. The voltage in this arc then rapidly decreases, so that the whole of the pressure is now impressed on the other side, so that the second arc is started. At the moment when the second arc is lighted, the circuit of the machine is directly closed through the two arcs in series, so that a long arc is formed. Certain modifications have recently been made. The voltage for starting the arc is much higher than is required in regular operation. The starting voltage is therefore now supplied by an auxiliary high-voltage but low-wattage circuit. It is feasible to operate any number of furnaces in parallel from the same circuit without any disturbing effect of one arc on the others.

The gases pass out of the furnace at a temperature of 700° to 800° C., and, after cooling, the oxides of nitrogen are converted into nitric acid and sodium nitrite. The heat of the escaping gases is, as already stated, used to pre-heat the air and also for concentrating the liquors. Sixty grams are produced per kw.-hour by the Pauling process. The present installation of twenty-four furnaces has a capacity of 15,000 h.p. Two other 10,000 h.p. are in course of construction, one in Northern Italy and the other in the South of France.

EXTENSIONS AT TUNBRIDGE WELLS ELECTRICITY WORKS

AT the invitation of Mr. Alderman B. M. Woollan, J.P. (Chairman of the Electricity Committee), the Mayor and Corporation, and a number of leading townspeople, paid a visit to the Municipal Electricity Works on Monday evening last to inspect the new turbo-generator which has recently been installed. Unfortunately Mr. Woollan was unable to be present, owing to indisposition, and his place was taken by Mr. Tylor, Deputy Chairman. The latest addition to the generating plant is a 500-kw. "Parsons-Westinghouse" turbo-generator running at 2,225 r.p.m., and supplying single-phase current at 2,000 volts, and this brings the total capacity of the station up to 2,150 h.p.

The actual figures for steam consumption of the new set obtained on test after correction were even better than those guaranteed by the makers, as follows:—

Consumption of Steam in lbs. per kw.-hour.

LOAD.	GUARANTEED.	ACTUAL.
¼	30·2	23·67
½	23·3	22·48
¾	20·8	19·58
Full	19·6	18·81

The set works with a vacuum of from 27 to 28 inches, up to 100° F. of superheat, and a steam pressure of 150 lbs. per sq. in. This new equipment was designed by the Consulting Engineer, Mr. H. P. Boot, and will no doubt effect great economies in the works costs.

On the occasion of the inspection the engineer had gathered together a considerable amount of electrical apparatus, with the help of the local contractors, including radiators, cooking utensils, arc lamps. The local wiring contractors are not numerous, but are high class and energetic, and have done a great deal by their efforts for the development of the supply department. In view of the fact that the charge for electric light is only 4½d. per unit, and the local gas is supplied at 2s. 8d. per 1,000 feet, it should only be necessary to make the precise comparative value of the figures known to the residents in order to secure a great extension of business. Current for power and heating is supplied at prices from 2½d. to 1¾d. per unit.

Amongst recent important additions to the load is the new skating rink, lit entirely with "Beck" arc lamps and Osram incandescents, and warmed with electric radiators. Power is also being used for keeping the floor in condition by means of sand-papering machines. A large local printing works is also

Digitized by Google

being fitted throughout with electric power and light, and several extensions are in progress in the residential districts.

From a *brochure* which has been compiled by Mr. J. W. Beauchamp, the Resident Engineer, giving particulars of the new plant, together with interesting notes on the metallic lamps, heating, cooking, and shop lighting, it appears evident that a serious attempt is being made to meet modern conditions, and to maintain the successful representation of the department which was always associated with Mr. Boot's management.

APPLICATIONS OF ELECTRICITY ON SHIPBOARD

At the annual dinner of the Institute of Marine Engineers last week, Mr. W. M. Mordey responded to the toast of "Kindred Associations," on behalf of the Institution of Electrical Engineers. He said that he sincerely hoped that in the future electrical engineers might be of even greater service to marine engineers than they had been in the past. He thought that he was one of the earliest engineers who had had to do with the introduction of electricity into ships. In 1882 he had helped to put into the old *Colossus* the installation of arc lighting, which he thought was the very first example of electric lighting of a warship in the world. Mr. Mordey then referred to the growing use of electricity for the auxiliary work on board ship, particularly on warships, and mentioned also the electrical propulsion of ships by interposing electrical machinery between the prime mover and the propeller, as a gearing between engines running at a high speed and a screw at a low speed. It was claimed, he said, that the advantages of such a combination, particularly with ships running at very varying speeds, would be found sufficient to justify the expense necessary; in fact, that the economies would be so great that the result would lessen the cost for the whole ship. Whether that was so or not it was too early to say, but he was glad to see in the Institute's journal that marine engineers are alive to the subject. Mr. Morley next suggested that of the 1,000 tons of coal or more consumed per day by some of the largest vessels in their passage across the Atlantic, possibly only 100 tons were really legitimately spent in driving the ship—the other 900 tons being used in an ineffective attempt to heat the Atlantic. He believed that the end of this century would see steam disappear, but did not know whether the future ships would be called "gassers" or "oilers," instead of steamers.

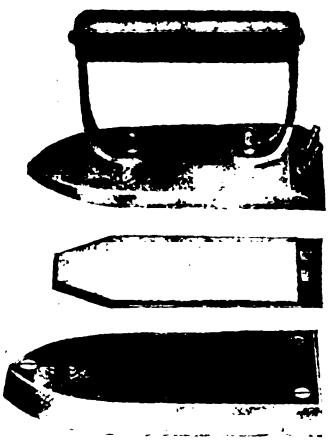
CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

ELECTRIC STOVES.—A leaflet from Messrs. F. A. Wilkinson & Partners, Ltd. (Harpenden, Herts), gives particulars of the Wilkinson economic electric stove, which can be used with ordinary household utensils, such as kettles, saucepans, flat irons, &c., and also for toasting. The apparatus, which can also be arranged for use as a radiator, was described and illustrated in ELECTRICAL ENGINEERING, May 13th, page 451.

METERS.—We have received from the Allgemeine Elektricitäts-Gesellschaft, of Berlin (whose London agents are the Electrical Co., of Charing Cross Road, W.C.), an illustrated reprint of a lecture by Herr Alex. Königswerther on electricity meters. All patterns of A.E.G. meters are described, from an instrument recording merely the number of hours an installation is being used, to the most highly developed A.-C. meters with double-tariff and other auxiliary attachments. An attachment for registering the maximum of the average demands taken over ¼-hour periods, a new prepayment meter, and the A.E.G. limit switch for use in installations supplied on the contract demand basis are also described.

IRON-CLAD MOTOR STARTERS.—A new illustrated catalogue is to hand from the Adams Manufacturing Co., Ltd. (106 New Bond Street, London, W.). This describes various patterns of "Igranic" iron-clad switchgear for direct-current motors. Each combination of starting and controlling gear is enclosed in one ventilated housing, making the panel immune from careless handling and complying with the latest Home Office regulations. The items listed include a number of patterns of wall and pillar type cases which are fitted with glass-fronted covers, and contain suitable patterns of starting rheostats and field regulators, together with the necessary fuses, automatic circuit-breakers, and other devices. A special multiple lever starter for large motors which have to start against heavy loads is described. In this starter there are no sliding contacts, the successive resistance steps being controlled by circuit-breakers with renewable carbon contacts.



A.-C. MOTORS.—A new set of price lists is to hand from the Langdon-Davies Motor Co., Ltd. (Southwark Works, Deverell Street, London, S.E.), relating to single-phase and polyphase motors of the short-circuited rotor and slip-ring type. Particulars and prices of single-phase motors of outputs varying from ¼ h.p. to 55 h.p., and for frequencies of 40, 50, 60, 80, and 100 cycles are given, and starters for these are also listed. These are high-speed motors with speeds of from 700 to 3,000 r.p.m., but prices of lower speed motors will be supplied on application. Two- and three-phase motors for 50 cycles and with outputs of from ½ h.p. to 85 h.p. are also listed.

ELECTRIC HEATING AND COOKING.—Two new catalogues dealing respectively with electric heating and cooking have just been issued by the Simplex Conduits, Ltd., and the completeness of each with the variety of articles included is a good sign of the progress being made in this branch of the industry. In the heater designs ample attention has been paid to the ornamental as well as the useful, both in the case of radiators and convectors. In the latter the Prometheus system is employed, in which thin resistance strips on light metallic frames are grouped in parallel, giving large surface per watt dissipated. The destructive effects of alternate heating and cooling met with in some wire-coil systems are avoided, and the self-induction is negligible. A similar form of heating element is used in the lighter patterns of heating and cooking appliances. The arrangement of the flat units is exemplified in the illustrations, which show the interior of a hot plate and a flat-

INTERIOR OF ELECTRIC HOT PLATE.

iron respectively. The flat open type of elements which are used for food-warmers, hot cupboards, &c., are connected in parallel, so that a mishap to one will not effect the working of the whole. For water-heaters, some types of kettles, the ring form of element, is employed, in which case the element is assembled round the hot well of the vessel. A small flat element is used on saucepans and the majority of kettles; whilst for flat-irons a flat element provided with spring "Z"-shaped terminals is employed. In all cases metal press plates are carefully constructed, having machined surfaces so that every portion of the strip may efficiently transmit the heat generated. Temperature regulation is fitted to all appliances of large capacity or of a more expensive nature. This is usually arrived

IRON TAKEN APART TO SHOW HEATING UNIT.

at by means of a special regulating plug, the latter made by means of three sockets, two black and one red, the former being connected to one pole and the red socket to the other pole. The four different positions put both circuits in parallel, both in series, or use one or the other alone. It is impossible to particularise the various appliances to which this system has been applied, embracing as it does so many designs of kettles, hot-water jugs, and other water-heaters, saucepans, frying-pans, bed-warmers, soldering irons, curling-iron heaters, irons, &c. A feature of the last mentioned is an automatic stand; the action of placing the iron on the stand completes the circuit, but when the iron is actually in use it is not in circuit. This has been found a more convenient arrangement for short, intermittent work than a trailing cable. The larger apparatus is constructed on the "Silundum" system, already described in ELECTRICAL ENGINEERING (July 15th, page 647), and here particular attention is given to restaurant equipments, including ovens, hot plates, grills, toasters, and combination apparatus, and steel hot cupboards for both food and plate warming, also urns, coffee machines, &c. Other appliances include geysers and hot-water tanks, sealing-wax heaters, glue pots, sterilisers, and mention should not be omitted of the fitting of special plugs to some of the appliances for use on different voltages.

LOCAL NOTES

BELFAST: *Centre Tramway Posts.*—It has been decided to change the tramway centre poles to side poles in a number of streets.

BRADFORD: *Extensions of Plant.*—Considerable progress is being made with the installation of two Curtis turbo-generating sets under the direction of Mr. T. Roles, the Borough Electrical Engineer. These each have an output of 3,000 kw., and are being installed by the British Thomson-Houston Co., Ltd. The condensing plant is being supplied by the Worthington Pump Co., as sub-contractors, and the two cooling towers are by the Crosthwaite Fire Bar Syndicate, Ltd. The machines are of the vertical type, but a temporary horizontal set has been installed.

BRAUNTON: *Electric Lighting.*—Negotiations are being carried on with Messrs. Crompton & Co., Ltd., with regard to the erection of a generating station.

BRAZIL: *Railway Electrification.*—Contracts are to be entered into for the electrification of the Central Brazil Railway. It is estimated that the change over of the railways to the third-rail system can be accomplished in two years at an estimated cost of £2,500,000.

BRIERLEY HILL: *Light Railway.*—An agreement has been drawn up between the British Electric Traction Co. and the Brierley Hill, Rowley Regis, and Quarry Bank Councils for the construction of a light railway between these three towns. The powers for the construction of the line expire at the end of the present year, and it is necessary to inform the Board of Trade that steps are being taken to put the Order into force in order to prevent the powers lapsing.

CLEVEDON: *Electric Lighting.*—Messrs. Christie Bros. are to apply for an electric lighting provisional order. An agreement is to be entered into between the Council and the company for the working of the Order for 5 years.

DARLINGTON: *Electric Wiring.*—The Corporation have decided to join in the promotion of a Bill suggested by the Maidstone Corporation in regard to securing electric wiring powers for municipalities.

DOVER: *S.P. Surface System.*—The Electrical Engineer and Tramways Manager have recently inspected the experimental track of the S.P. Syndicate, Ltd., of Southall, but report that as the system has not yet emerged from the experimental stage, it would be advisable to await further developments and improvements.

DUNFERMLINE: *Tramway Inspection.*—Extensions of the Dunfermline & District Tramways were inspected on behalf of Board of Trade last week. The Inspector was asked by a deputation from the Town Council to use his influence with the Board of Trade in order to insist upon a further extension of the lines to Lochgelly, a distance of two miles.

EGYPT: *Electric Motor-cars.*—According to an American Consular report, electric motor-cars running in Alexandria and Cairo are exempt from registration and numbering.

GILLINGHAM: *Electric Wiring Powers.*—In reply to the Maidstone Corporation, who have asked the Council to co-operate in the promotion of a one-clause Bill applied to municipalities not already possessing electric wiring powers, the Council have asked for further particulars as to the number of boroughs who are prepared to take the matter up, and what the individual expense is likely to be.

HARWICH: *Parkeston Quay Extension.*—In connection with the extension to Parkeston Quay, which is now almost completed, two turbo-alternators have been added to the Great Eastern Railway Co.'s power station for the purpose of lighting and power supply. A number of electric cranes have been installed, and considerable extensions to the supply mains have been rendered necessary. Mr. H. W. Firth, the Electrical Engineer to the Great Eastern Railway Co., has been responsible for the electrical portion of the extension to the quay.

HESTON AND ISLEWORTH: *Electrical Pupils.*—The Council have inaugurated a system of pupilship in the electricity department. The pupils are selected after open examination, and are officially recognised by the Council.

ILFORD: *Tramways and Electricity Undertaking.*—The Council have decided to separate the tramways from the electricity undertaking. A tramways manager is to be appointed to deal with the tramways alone. Mr. Woolstencroft, who for some years has been the tramways superintendent, has been given the management *pro tem.*

KETTERING: *Electricity Loan.*—The Liverpool Victoria Legal Friendly Society have advanced the Corporation a loan of £2,000 for electrical purposes.

KINGSTON-ON-THAMES: *Electricity Accounts.*—The accounts of the electricity undertaking, given in our issue for October 28th, and which show a deficit of £1,251, were discussed at the meeting of the Corporation last week. Several Councillors expressed the opinion that the time had arrived for taking steps to put the undertaking on a sound financial basis, but the chairman of the Electric Lighting Committee asked the Council to postpone any drastic action for another year, when he thought they would be able to show that the undertaking was making substantial progress.

LITTLEBOROUGH: *Electric Supply.*—An agreement is being entered into with the Rochdale Corporation for a supply of electrical energy.

LONDON: *London County Council: Tramways.*—Arrangements have been made for a through service of cars between Aldgate and Ilford Broadway. The managers of the West Ham, East Ham, Leyton, and L.C.C. systems have agreed upon the service being run on a basis of equal earning value over the whole of the lines.

The Highways Committee recommend that application be made for Parliamentary powers for additional tramways in Herne Hill and Greenwich.

In order to test the working of a special brake for use on the Highgate Hill tramways, a short length of track is to be laid at the Central Car depot in Woolwich, with the slot rail raised above the surface of the track.

MORECAMBE: *Electrical Engineer.*—At the last meeting of the Corporation, reference was made to the advertisement for a new borough electrical engineer at the low salary of £150. It was urged by some of the councillors that a really responsible official should be appointed at an adequate salary, and that the service of a consulting engineer should be dispensed with. Difficulties were foreseen in regard to the management of the works with two officials nominally responsible for them. A proposal to rescind the resolution to advertise for an electrical engineer at a salary of £150 per annum was rejected by 11 votes to 9. The capital expenditure at Morecambe amounts to £60,000.

NEWCASTLE: *Tramways.*—Sir J. B. Ellis has resigned the Chairmanship of the Tramways Committee.

OLDHAM: *Charge for Tramway Energy.*—The Electricity Committee recently offered to reduce the price of energy for tramway purposes from 1½d. to 1¼d. per unit on condition that the full tramway service was reinstated, a reduction in the car-mileage having recently been made which has affected the quantity required by the tramways department. In a report upon this offer, the Tramway Manager is entirely unfavourable to the suggestion on the ground that the reduction would not counterbalance the extra consumption necessary if the original service was reinstated. The Tramways Committee, therefore, propose to take no action with regard to the offer.

WEDNESBURY: *Electric Lighting Loan.*—A loan of £2,546 is to be taken up from the Wesleyan & General Assurance Co. for 25 years at 3¾ per cent. per annum.

YORK: *Electricity Accounts.*—The total revenue from the electricity undertaking for the year to March 31st amounted to £18,119, and the gross profit was £8,642. After meeting capital expenditure, there is a balance of £853, which reduces the deficit on the undertaking to £5,935.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AMBLE.—The report of Mr. Cecil Esmarch, Consulting Electrical Engineer to the Council, puts the approximate cost of an electrical installation at £4,162. The annual charges are put at £668, including interest, and the revenue at £765 per annum.

ARGENTINE.—The *Review of the River Plate* states that the Rosario Electric Co. intend constructing a generating station in Sorrento for dealing with the northern suburbs. The estimated cost is about £200,000.

The Santa Fé Municipality are calling for tenders for electrical machinery.

BELFAST.—A report has been prepared by the Electrical Engineer dealing with extensions to plant.

BIRKDALE.—The Local Government Board is to be asked to sanction a loan of £375 for the purpose of extending the mains into the Ainsdale district.

BURTON-ON-TRENT.—The Local Government Board has sanctioned the borrowing of £4,000, to be laid out as follows:—£2,900 for mains and feeders; £650 for services; and £100 for switchgear and instruments.

COOKSTOWN (IRELAND).—The Council are urged to take the necessary steps to supply electricity for public and private purposes.

DONCASTER.—Mains are to be extended for the purpose of supplying Bentley Village.

EDMONTON.—Tenders are invited by November 25rd for lead-covered cables and switchboard for the new infirmary. Particulars from Messrs. May & Hawes, Caxton House, Westminster.

Digitized by Google

HANTS.—£846 is to be expended on additional electric plant and a calorifier at Fareham Asylum, the total mentioned being made up as follows:—90 h.p. engine, estimated cost, £376; 300 amp. dynamo, £270; calorifier, £200.

LONDON: *Islington.*—The Finance Committee of the L.C.C. recommend sanction to a loan of £2,985 for mains, house service, and meters.

NEWCASTLE (IRELAND).—Mr. A. E. Porte, Electrical Engineer of Belfast, has been appointed at a fee of 10 guineas to prepare a report upon an electric lighting scheme.

RHYL.—The Local Government Board held an inquiry last week concerning a loan of £5,000 for electrical purposes. The Borough Electrical Engineer stated that the present plant was out of date, and that what was required was a smaller plant of an up-to-date pattern.

SOUTH AFRICA.—The Durban Town Council is applying for powers to borrow large sums for improvements during the next five years. The sum of £100,000 is to be borrowed for electric supply purposes, and £60,000 for tramways.

WHITCHURCH.—The Local Government Board have sanctioned a loan of £2,960 for electric lighting purposes in Whitchurch. The Llandaff and Dinas Powis Rural District Council are taking a supply from the South Wales Electrical Power Distribution Co. for distribution in Whitchurch.

Miscellaneous

BIRMINGHAM.—Tenders are invited by November 20th for the maintenance of the private telephone installation at the Birmingham Workhouse, Dudley Road. Particulars from the Master.

DUBLIN UNITED TRAMWAYS CO.—Tenders are invited for stores, including electrical supplies. (See advertisement on another page.)

RHONDDA.—Parliamentary powers are to be sought for considerable extensions of the local tramways system.

LONDON: *London County Council.*—Tenders are invited by November 30th for covering with asbestos tape about 2¾ miles of lead-covered high- and low-tension cables in manholes. Particulars from the Clerk.

Port of London Authority.—Tenders are invited by November 22nd for general stores, including incandescent electric lamps and arc lamp carbons. Particulars from the Secretary, 109 Leadenhall Street, London, E.C.

NORTH EASTERN RAILWAY CO.—Tenders are invited by November 25th for stores, including arc lamp carbons, electric lamps, electric wires and cables, and electric light fittings. Particulars from the Secretary, York.

PLYMOUTH.—Mr. T. N. Riley, engineering master at the technical school, recommends the provision of electrical machines, measuring instruments, and regulating resistances at a cost of £225.

SWEDEN.—A Swedish engineer has drawn up a project for the construction of an electric railway from Malmo to Copenhagen, passing under the Sound. The line will be about 147 miles long, with about 10 miles of tunnel. The project has been submitted to a special commission appointed by the Swedish Government.

WAKEFIELD.—The Wakefield and District Railway Co. invite tenders by November 25th for general stores, including electric lamps and fittings, insulating materials, and overhead fittings. Particulars from the General Manager.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

S.E.—School, Sherington Road, Greenwich (£13,212). Builders, W. Johnson & Co., Ltd., Wandsworth Common, S.W.

S.W.—School, Waldron Road, Wandsworth, S.W. (£5,430). Builders, J. & M. Patrick, Wandsworth, S.W.

Conversion of granary into offices at the premises of the London General Omnibus Co., Ltd., Page Street, Westminster, S.W.

W.—Hospital (£16,526), Ealing. Builder, W. J. Dickens, Helena Chambers, Ealing, W.

PROVINCES.

BOURNEMOUTH.—Science, art, and technical schools (£19,055). Architect, T. W. Lacey, Municipal Buildings, Bournemouth. Builders, J. & M. Patrick, Wandsworth, S.W.

BRADFORD.—Test-house, Daisy Hill, for the Guardians (£7,000). Architect, F. Holland, Manor Road, Bradford.

BRISTOL.—Adaptation of premises for school (£2,445). Builders, R. F. Ridd & Sons, 18 Wilder Street, Bristol.

DUDLEY.—School (£4,400). Secretary, Education Committee.

EDINBURGH.—Veterinary college (£40,000). Architect, D. McArthy, 25 Frederick Street, Edinburgh.

Tenders are invited by November 23rd for the wiring of the M'Leod Street Police Station. Particulars from the Town Clerk.

EXETER.—Boys' school, Cowick Street (£2,300). Architect, P. Morris, 1 Richmond Street, Exeter.

Additions to infirmary. Clerk to the Guardians.

FARNWORTH.—Library, Market Street. Architect, J. Lomax, 11 Fold Street, Bolton.

GLASGOW.—Nurses' home, Belvedere Hospital (£3,000). A. B. McDonald, City Engineer, Glasgow.

GRIMSBY.—School, Strand Street (£11,200). Builder, W. Kirton, Grimsby.

ILFRACOMBE.—Restaurant on promenade (£3,000). Architect, A. T. Hussell, Market Square, Ilfracombe. Builder, R. Picketts, Ilfracombe.

KEIGHLEY.—Additions, workhouse infirmary (£2,000). Architects, Moore & Crabtree, Keighley.

MANCHESTER.—Diocesan Church House, Deansgate. Architect, John Brooke, Exchange Street, Manchester.

NORTHAMPTON.—Extensions to Northampton Town and County School, Biling Road (£2,250). Architect, c/o Clerk, Northampton Town Council.

PLYMOUTH.—Arcade, Market Lane, for Spooner & Co., Ltd. Architect, A. S. Parker, 20 George Street, Plymouth.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The tender of Messrs. W. Sim & Co. has been accepted by the Prahran & Malvern Tramways Trust for tramway permanent way and poles at £18,780. The tender of the British Insulated & Helsby Cables Co., Ltd., for overhead construction, feeder cables, &c., at £5,502 has also been accepted.

BURY.—The tender of Messrs. E. Green & Son has been accepted for the supply and erection of economisers at the new power station.

KETTERING.—A contract has been entered into with Messrs. E. Bennis & Co., Ltd., for the supply of a mechanical stoker.

KILKENNY ASYLUM.—Messrs. Meguire & Gatchell, Ltd., of Dublin, to whom has been entrusted the electrical installation of this asylum, have placed the order for the necessary storage battery of 120 cells with the D.P. Battery Company, Ltd., of Bakewell.

LEYTON.—The tender of Messrs. Johnson & Phillips, Ltd., has been accepted at £143, for the installation of electric light at the Canterbury Road Schools. Twenty tenders were received, the prices ranging from the one accepted to £312.

LONDON: *London County Council.*—The tender of Messrs. Davy Bros., Ltd., at £2,818, for the supply and erection of two marine type boilers with coal elevator, machine stokers, induced draught and air heating apparatus in connection with the first extension of the Tramways Central Car repair Depot.

A contract has been entered into with Messrs. W. T. Henley's Telegraph Works, Ltd., at £2,200 for extra work in connection with the underground telephone system in use between the various sections of the tramways department.

Metropolitan Asylums Board.—Orders have been placed as follows:—J. W. Gray & Sons, re-establishing telephonic connection between Gore House and the hospital, £56 10s.; W. J. Fryer & Co., two electric motors, with cables, switches, &c., £129 18s.

NORTHAMPTON POLYTECHNIC, CLERKENWELL.—The storage battery and automatic reversible booster balancer set required in connection with the electrical equipment of this Institution, are being supplied by the D.P. Battery Co., Ltd., Bakewell.

SHEFFIELD.—The Council have accepted the tender of the British Insulated & Helsby Cables, Ltd., for two miles figure 8 copper trolley wire at 7⅞d. per lb., less 2½ per cent.

SPAIN.—The Spanish Arsenal has placed an order with Messrs. Drake & Gorham, Ltd., for 50 of their new registered pattern shuntless single enclosure lamps.

WISHAW.—The tender of Messrs. Ferranti, Ltd., for a switchboard at the Council's sub-station, has been accepted at £150.

THE following are among recent orders received by Messrs. Royce, Ltd., Trafford Park, Manchester: 2 45-ton overhead electric cranes for Canada; 2 125-ton electric cranes for a Japanese dockyard; and 23 electric capstans for the Clyde Navigation trustees, 14 of the latter being of the "Royce" patent free barrel type.

New Electric Railway in Hamburg.—It is stated that the combined underground and elevated railway, which is being constructed in Hamburg by the Allgemeine Elektricitäts-Ges. and the Siemens & Halske Akt.-Ges., will be opened in 1911. The length of the line will be 17 miles of double track, over four miles of which will be underground. It will be a continuous-current railway with current supplied from a third rail at 800 volts. Two sub-stations will transform the current from 6,000 volts alternating, at which pressure it will be received from a steam turbine power station outside the city.

COMPANIES' MEETINGS AND REPORTS

DEUTSCHE GASGLUHLICHT AKT.-GES. (AUERGESELLSCHAFT).—The report for the year 1908/9 records a net profit of 4,038,199 mk. (approx. £201,900), including 510,080 mk. brought forward from the previous year. A dividend of 50 per cent. on the ordinary shares is proposed, against 35 per cent. last year. The full dividend of 5 per cent. is proposed on the preference shares. A sum of 38,199 mk. is carried forward. The prospects of the current year are said to be favourable. The general meeting will be held in Berlin on December 1st next.

ALLGEMEINE ELEKTRICITATS GES.—Although the balance sheet has not yet been completed, the results of the past year's working are announced to have been extraordinarily favourable. A dividend of 13 per cent. is announced.

AMAZON TELEGRAPH CO.—For the year to June 30th there was a profit of £1,690, which reduces the debit balance to £49,380.

EDISON & SWAN UNITED ELECTRIC LIGHT CO.—At the meeting last week, the report and accounts given in our issue for October 21st were adopted. Mr. H. Wolfenden, the chairman of the company, presided, and said that the large decrease in the profits was due to the decline in the price of carbon lamps, with which they had been principally dealing during the year. There had not, however, been a corresponding reduction in the cost of manufacture and distribution. The production of carbon filament lamps had now been reduced owing to the increase in the demand for metal filament lamps. They thought, however, that there would always be a field for the use of carbon lamps.

VENEZUELA TELEPHONE & ELECTRICAL APPLIANCES CO.—For the year to June 30th, 1909, there was a net profit of £4,846, which is to be carried forward.

NEW COMPANIES

A. A. RUPPRECHT & CO.—Registered on October 15th, with a capital of £1,000, to carry on the business of mechanical, electrical, and general engineers, electricians, machinists, founders, &c. Private company. Registered office, Carlton House, Regent Street, S.W.

MAGNETO CO.—Registered on October 21st, with a capital of £500, to acquire the business belonging to H. W. van Raden and J. J. Horne, formerly carried on by them at Dreadnought Works, Phillip Street, Aston, as the Magneto Co., and to carry on the business of magneto and electrical manufacturers, dealers, and inventors, manufacturers of and dealers in motor-cars, engines, and fittings, &c. Private company. Registered office, Dreadnought Works, Phillip Street, Aston.

MARBRO.—This company was registered on October 27th with a capital of £2,000 in £1 shares (1,500 pref.), to carry on the business of manufacturers of electrical goods of all kinds, general merchants, &c. Private company. Registered office :—22 Belsham Street, Morning Lane, Hackney, N.

FELD BROTHERS & COMPANY.—Registered on October 25th, with a capital of £5,000, to acquire the business carried on at 432-433 Mansion House Chambers, E.C., as Feld Brothers, and to adopt an agreement with F. W. Sichtermann and A. Feld, and to carry on the business of manufacturers of and dealers in electrical appliances, lamps, burners, fittings, radiators, batteries, cables, wires, accumulators, motors, and engines, &c. Private company. Registered office :—432 and 433 Mansion House Chambers, Queen Victoria Street, E.C.

HOWE ELECTRICAL ENGINEERING CO.—Registered on October 22nd, with a capital of £5,000, to take over the business carried on at 16 Redcross Street, and 14A Moor Street, Liverpool, and at 24 New Road, Blackburn, as the "Howe Electrical Engineering Co." Private company. Registered office :—Mersey Railway Buildings, 18 James Street, Liverpool.

BROWN & MURRAY.—Mildmay Park Works, Islington. Capital, £1,000 in 900 preferred ordinary, and 100 founders' shares of £1 each. To take over business of S. G. Brown & D. Murray, known as Telegraph Machinery Manufactory.

SMITH, MAJOR, & STEVENS.—Janus Works, Queen's Road, Battersea. Capital, £50,000. To take over business of Messrs. Archibald Smith & Stevens, electrical and mechanical engineers, &c.

VACTITE WIRE CO.—805 Salisbury House, London Wall, E.C. Capital, £450. To take over business of the Vactite Wire Co. (Incandescent Electric Lamp Accessories, 50 Uxbridge Road, Ealing).

WAKELIN BROS.—5 and 7 Tottenham Street, Tottenham Court Road, London. Capital, £2,000. To carry on business of electrical and general engineers.

APPOINTMENTS AND PERSONAL NOTES

Applications are invited by November 25th for the position of Borough Electrical Engineer to the Morecambe Corporation. Salary, £150 per annum. Particulars from the Town Clerk.

MISCELLANEOUS CITY NOTES

CORDOBA LIGHT, POWER, & TRACTION CO.—A new issue of debenture capital is being made with the object of extending the various portions of the company. A new concession has been granted for 40 years, and steam generating plant is to be added to the existing water-power plant. A contract has been entered into with Messrs. J. G. White & Co. for the conversion of the horse-tramways to electric traction.

WEST INDIA & PANAMA TELEGRAPH CO.—A dividend of 6s. per share for the June half-year is recommended on the first preference shares, and 20s. per share on the second preference shares.

COMPANIES TO BE STRUCK OFF REGISTER.—The names of the following companies will be struck off the register at the end of three months unless cause is shown to the contrary :—Adelaide Electric Tramways; Automatic Electric Co.; Bettwsycoed Electric Lighting Co.; Burmah Electric Works Syndicate; Cleminson Electric Lamp Attachment; Diamond Electric Lamp; Electrical & Hardware Co.; Electrical Bleaching Co. (1904); Electromotion Corporation; Manchester & Liverpool Electric Railway Syndicate; Perth Electric Lighting Co.; River Po Electric & Power Syndicate; Wynne's Electric Closed Tube Tramways.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons. of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 to £60 10s. per ton (last week, £59 5s. to £59 15s.)

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Solium Electrical Company, Ltd., is to be wound up voluntarily. Mr. Edward Harlow, 23 King Street, Nottingham, is liquidator. A meeting of the creditors will be held at this address on November 12th at 12 noon.

The first meeting in the bankruptcy of Ernest Goodman, electrical engineer, 30 Hertford Street, Coventry, will be held at the Official Receiver's Offices, 8 High Street, Coventry, on November 15th at 3 p.m. The public examination will take place at the County Hall, Coventry, on December 6th, at 2.30 p.m.

EXTENSION OF PREMISES.—Messrs. G. M. Boddy & Co., of London, Liverpool, Sheffield, and Manchester, are extending their London premises, having taken over the building 15 Gray's Inn Road, lately occupied by the Electro Motor & Dynamo Co. (whose business has been taken over by Messrs. J. & H. Grevener). Messrs. Boddy & Co. inform us that they will now be better able to give early deliveries of their lamps.

NEW PUBLICATIONS

"Science Abstracts." October. Section A : Physics; Section B : Electrical Engineering. (London : E. & F. N. Spon.) Price 1s. 6d. each.

"The Mechanical World" Electrical Pocket Book for 1910. (Manchester : Emmott & Co., Ltd.) 6d.

"Electric Power Conductors," by W. A. Del Mar. (London : Crosby Lockwood and Son.) 9s.

Telegraph Traffic.—When the submarine cable between Chafarinas and Nemours was opened in 1908, it was reserved for certain correspondence, but it may now be used in the event of an interruption for any telegrams.—A new telegraph office has been opened in German West Africa at Buiko, as well as another at Yozema in Sierra Leone.—The line between Bagdad and Bassorah was broken on the 3rd inst. for a short while.—The Direct Spanish Telegraph Co. reports the failure on the 2nd inst. of the cable between Falmouth and Bilbao. The interruption was probably caused by the anchor of a vessel. A steamer will have to be chartered to repair it, as the company does not own one.—The Compagnie Française des Cable Télégraphiques reports the breaking of the connection with Brazil by the failure of the cable between Cayenne and Salinas. Messages for the latter place will be sent forward by the best means without alteration of rates.—On the 3rd inst. also the cable between Réunion and Mauritius ceased working. So far as we are aware, this is the first break which has occurred to this line since it was laid. The islands are still in telegraphic communication, the former with Madagascar and the latter *viâ* the Seychelles.—Communication both by cable and land-line between Saigon and Tonkin was interrupted on the 4th inst.—On the 5th inst., the line between Rome and Constantinople was down, but was repaired on the 7th.—On the 6th inst., the Direct Spanish Telegraph Co. were again able to work their cable between Falmouth and Bilbao.—The El Arich route was interrupted between Konia and Adana on the 7th inst.—Persian lines are also experiencing trouble, for on the 8th the telegraph line to Ahvaz and Mohammareh was down, and messages have to be posted at Boraz Joon.—An unfortunate hurricane has struck the Island of Jamaica, apparently doing damage to land-lines, as notice of delay to this island has been issued.—The Haytian land-lines are also interrupted.

REVIEW

Modern Electric Practice. Edited by Dr. Magnus Maclean, M.A., D.Sc. New Edition. Six Vols. 10 ins. by 6½ ins. 1,769 illustrations. (London: The Gresham Publishing Co.) £2 14s.

THE object of the series of six volumes before us is to cover, in as complete a manner as is reasonably possible, the whole range of the present-day aspect of electrical engineering; and it is intended more to form a compact electrical reference library for the practical man than to provide a course of instruction for the student. A task of this magnitude would be impossible of satisfactory performance by a single writer, and the main value of the work lies in the fact that the various sections are written by a group of some thirty-eight authors, many of them specialists of the first order in the portions of the subject with which they deal, under the general editorship of Prof. Magnus Maclean.

The subject is divided up into five sections as follows:—(1) The Measuring, Generating, Transforming, and Storing of Electric Currents; (2) Electric Lighting and Power Distribution; (3) Electric Traction; (4) Boilers and Motive Power Engineering; and (5) Miscellaneous Applications of Electricity. The sections do not coincide with the volumes, as might have been more convenient for reference, but these have been kept of approximately equal size, irrespective of the grouping of the main sections. Thus Vol. I. does not contain the whole of Section I., but is made up of the sub-sections on measurements, generators, and continuous-current motors. The opening portion is by Dr. A. Hay, and is entitled "Electric and Magnetic Measurements." The main principles and properties of currents and magnetic flux and their interaction are outlined, and, proceeding to further detail, the usual methods of measurement are set forth and a number of test-room and ordinary instruments are described, most of which are of fairly modern type. The chapter on magnetic testing, however, is not quite representative of the methods in use. The final chapter in this sub-section, on primary batteries, is commendably short, and avoids the very common fault of unnecessary descriptions of obsolete apparatus. It is surprising, however, that the reference to dry cells, which are much more extensively used than most of the cells described, is limited to two lines.

The sub-section on alternating currents is by Prof. E. W. Marchant, and, commencing with a chapter on the Duddell oscillograph, outlines in a clear way the principles of alternating currents, and describes the action of various alternating-current instruments, including a representative collection of supply meters. This is followed by a sub-section on continuous-current generators, by Messrs. W. C. Mountain and J. Leggat, of a thoroughly practical nature, embracing points of mechanical as well as electrical design, and including data and drawings of modern machines with and without interpoles. Among them are examples of continuous-current turbo-generators, and in connection with these latter the Deri system of compensation is gone into as well as the use of commutating poles. A certain amount is also said here about turbo-alternators, although the subject of alternators should have been reserved for the next sub-section, by Messrs. E. J. Berg and W. B. Hird. A similar treatment is given by these authors of the alternator, including short chapters on induction generators, inverted converters and double-current generators, and motor generators and rotary converters. The last, which is somewhat disappointing in its shortness, is little more than a comparison between the motor-generator, rotary converter, and motor converter; neither of the last two has, up to this point in the book, been satisfactorily described. Mr. A. T. Snell concludes this volume with the design of continuous-current motors, and gives illustrations of their applications, including some interesting particulars of continuous-current electric lift practice. Inside the back cover is an ingenious set of coloured cardboard sectional models of a continuous-current motor.

Messrs. M. B. Field, G. G. Braid, and Dr. J. R. Goldschmidt are joint authors of three chapters on A.-C. motors, which commence the second volume of the work. The essential differences between synchronous and asynchronous motors are first made clear, and a remarkably lucid exposition is given of the principles of the rotating field, particularly as regards the Heyland single-phase induction motor. The next chapter is devoted to principles of construction and operation, including some remarks on the rotary converter, a subject also treated in the transformer section of the book, and the last one contains a graphical treatment of the theory of A.-C. motors, including a somewhat brief sketch of the action of the single-phase commutator motor founded on the work of Dr. R. Goldschmidt, of Darmstadt. Commutator motors of the repulsion type, however, are not included under this heading, but immediately precede it, and, indeed, this part of the subject is not treated with quite the same completeness as that relating to the older types.

There are probably few people more competent to write on transformers than Mr. A. F. Berry. He contributes four excellently-written chapters on the "static" transformer, mainly from the designer's point of view, and one of a thoroughly practical nature on transformer connections, and notes on working. The same writer is responsible for a chapter on the rotary converter, but, owing probably to considerations of space, this is rather incomplete, and some recent developments, such as the split-pole converter, and several controversial points, have been obliged to remain untreated. We should certainly also have expected to see in either this section or that on alternating motors a description of the La Cour motor-converter, which has proved so successful a competitor to the single-armature rotary converter.

A short treatise on storage batteries, by Mr. J. T. Niblett, brings the first section to a close at about the middle of the second volume. Although it does not enter very deeply into the chemistry of the subject, it will doubtless be appreciated by the engineer who is desirous of obtaining a fairly complete idea as to the construction of the secondary cell. This chapter would have been improved by a clearer discrimination between those cells that are the chief types in use at the present day and those which have not survived to become practical appliances for everyday commercial use. Some excellent illustrations showing the construction of plates alternate with large and ungainly general views of cells which are quite out of place in a book of this character. We sympathise with the editor in the difficulty he must have experienced in sub-dividing the various subjects in such a way that nothing of importance should be omitted Perfection in this respect is well-nigh impossible, and we notice with regret that the methods of employing storage batteries in central stations, the connection of regulating cells, and the construction and use of boosters have been left out entirely.

Section II. of "Modern Electric Practice" opens with a fine collection of illustrations of switches, switchgear, and diagrams of connections. Mr. W. E. Warrilow, the author of this part of the book, has evidently known where to go for some of the most perfect pictures of this class of apparatus, but the letterpress for the most part reminds one of a lantern lecture; the actual design and construction of switches and switchgear is only dealt with superficially.

In striking contrast to this are the chapters on "Electric Mains," by Mr. J. C. A. Ward, of Callender's, with which the second volume is concluded. The matter has been systematically arranged, and from beginning to end bears evidence of the writer's practical experience in the subject. After a brief description of the various classes of cable, the methods of laying are dealt with, and suitably illustrated with carefully selected drawings and without repetition. Next follows a chapter to explain the necessity of earthing and bonding, and the methods of carrying it out, and chapters on fusing and balancing networks, localising faults and jointings, the last-mentioned chapter including useful drawings of junction-boxes and feeder pillars. The final chapter, on mining cables and accessories, is full of practical hints and sound advice.

The calculation of the sizes of conductors is not dealt with by Mr. Ward, but is treated briefly by Mr. W. W. Lackie (Engineer-in-Chief of the Glasgow Electricity Department) in the second part of Vol. III., "Electric Lighting and Wiring." In this chapter the general principles of wiring are explained, and descriptions are given of the various materials and accessories employed; rather undue prominence is given to illustrations of a particular system of concentric wiring. Preceding this chapter is a contribution by Mr. W. B. Esson on "Distribution and Transmission of Electric Energy." This sub-section includes electricity supply works, and we should have welcomed more detailed consideration of the design and equipment of the class of steam-driven stations which prevail in this country; water-power stations and overhead transmission lines receive undue prominence. The difficulty of writing on "Electric Fittings" has been overcome by Messrs. G. Byng and V. Zingler by dividing the subject into five chapters: Historical, Technical, Manufacture, Art, and Types of Fittings and their Uses. "Arc Lamps," by Mr. F. Biliotti, is not quite up-to-date.

The contribution on "Incandescent Lamps," by the late Mr. C. J. Robertson, is exceedingly interesting, and contains much with regard to manufacture that is not known to the general electrical engineering public. For obvious reasons Mr. Robertson has not given away too many details with regard to the making of tungsten lamps, but the reader gets as much or more than he has any right to expect. Moreover, even if the chapter upon metal filament lamps had included an absolutely complete account of their manufacture up to the date at which it was written, it would still have been incomplete by the time the book was printed and published, so rapid has been the progress made in this industry during the past year.

"Electric Traction" commences in Vol. III., although the

Digitized by Google

greater part is contained in the following volume. Mr. J. R. Wignall is responsible for the chapters on rails, which conclude with a bill of quantities and estimate for a mile of single standard-gauge track, and Messrs. Victor Watlington and G. G. Braid write from experience on bonding. The remainder of the subject is dealt with in Vol. IV., which commences with some chapters on overhead construction, by Mr. I. E. Winslow. These include, besides descriptions of a variety of fittings, &c., a good deal of information on poles and pole setting which is not often found in text-books. The same author has also an excellent section on tramway feeders, which is followed by one over fifty pages in length on surface-contact systems. In proportion to the treatment of some other subjects, altogether too much space is given to these. Over forty systems are illustrated and described, the large majority of which have never proceeded further than the Patent Office or have proved failures in practice. Yet the G.-B. system, which is certainly one of the most important, has been entirely omitted. The succeeding chapter on conduit systems, by Mr. A. G. Seaman, suffers to some extent from the same fault, but this is redeemed largely by the excellent illustrations of details of some really modern systems, including that of the London County Council. A good practical section, by Mr. H. C. Buckmaster, on rolling stock and equipments follows, after which are two chapters on electric motor-cars and motor-boats, by Mr. W. Worby Beaumont. Even so well known an authority has not had the courage to omit matter used in former editions which is now only of historical interest; while, on the other hand, the important subject of "petrol-electric" transmission is dismissed very briefly. An interesting feature of the motor-boat chapter is the inclusion of submarines, but naturally conditions of Admiralty secrecy prevent any pretentions to this being up-to-date. The consequence of the presence of so much redundant matter is that only seventeen pages are allowed to Mr. Philip Dawson to treat the important subject of electric traction on railways, but, needless to say, he presents an admirable *résumé* of the present state of the subject, and it is perhaps natural that a considerable portion of the space is allotted to single-phase working.

Vol. V. contains the whole of Section IV., "Boilers and Motive Power Engineering," and the names of the authors, Mr. J. K. Stothert (of Babcock & Wilcox), Mr. H. O. Beckh (of Davy, Paxman & Co.), Mr. J. Campbell, and Mr. W. H. Booth, are a sufficient guarantee of its excellence. At the end of this volume are also two chapters, by Mr. J. Shields, on electrochemistry and electrometallurgy. Although he gives us plenty of information regarding processes for the manufacture of aluminium, calcium carbide, carborundum, graphite, and electrolytic copper refining and alkali processes, Mr. Shields does not appear to realise the enormous developments that are now being made in the refining of iron and steel by the electric furnace.

Vol. VI. completes the "Miscellaneous" Section. Mr. A. C. Booth (of the Post Office) and Mr. Dane Sinclair (of the British Insulated & Helsby Cables, Ltd., and formerly Engineer-in-Chief of the National Telephone Co.) were obviously able to write well and to the purpose on telegraphy and telephony if they took the trouble, and they have taken the trouble. The clear diagrams call for special praise. Many of our readers will not share the preference for continuous-current and vulcanised rubber cables expressed by Mr. Daniel Burns in "Electricity in Mining." His contribution includes descriptions of a large number of coal-cutters, and deals at some length with haulage and pumping. Winding is dealt with very briefly, and there is no mention of the Ilgner system. The remaining sections are on electric cranes (by Mr. Philip Dawson), electromedical appliances (by Dr. Dawson Turner), and railway signalling (by the late Mr. W. E. Langdon).

This volume also contains an excellent index to the whole work.

No collection of this magnitude can be absolutely perfect, and, although it has been our duty to criticise here and there, the six volumes, considered in their entirety, reach a standard of excellence which is rarely approached in encyclopædic productions of this character. The engineer is nowadays almost invariably a specialist, and he has frequently to search for information or to refresh his memory in other branches of the profession than his own. For this purpose "Modern Electric Practice" is destined to be of the utmost utility. We congratulate the Gresham Publishing Co. and Dr. Magnus Maclean on having produced a work of very great value which should find a place in every electrical engineer's library.

Physical Society's Exhibition.—The date of the annual exhibition held by the Physical Society of London, which was originally fixed for December 10th, has been altered to Tuesday, December 14th, so that the exhibition may be open in the afternoon as well as in the evening.

MUSIC-HALL ELECTRICITY

ON Thursday, the hearing of the action brought by Mr. C. H. Irving against S. M. Bodie for the recovery of £1,000 paid as premium, was concluded; the jury returned a verdict against the defendant. We dealt fully with the facts of the case in our last issue.

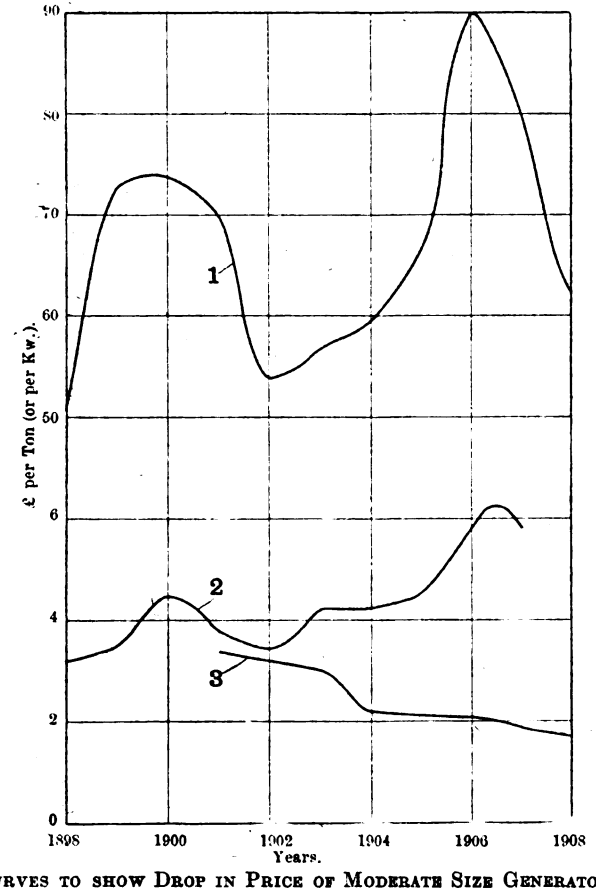
It will be remembered that Bodie's counsel obtained on the Wednesday permission from Mr. Justice Darling, before whom the case was being heard, to allow the defendant to give a private demonstration of his ability of sustaining high pressures before the jury, a representative from either side, and an expert electrician appointed by Mr. Justice Darling. Previous to this demonstration, Bodie gave evidence to the effect that he used three sets of electrical apparatus: first, an ordinary high-frequency set, which he admitted was not dangerous at all; secondly, a 12-in. spark coil, from which, he said, he could take a shock at 60,000 volts, dangerous to anybody but himself or his assistant, as they had trained themselves to withstand it; and thirdly, a large solenoid, which he used at the ordinary supply pressure, and named the "cage of death." With this last apparatus, he said, he completed the circuit through his body, with iron rods held in his hands, and took a current of "20 amperes" from the direct-current supply mains. This, he said, was "rather risky." Bodie admitted that he used fireworks to heighten the effect of the "cage of death." He also admitted that he used the large magnet purely to impress the audience. At the demonstration before the jury he did not produce the "cage of death," but he took a shock from his induction coil. The electrician appointed by Mr. Justice Darling was Mr. A. Strich, a director of the Sanitas Electrical Co., Ltd., who stated that Bodie had received a shock from the 12-in. coil, which, however, was only giving a 6-in. spark at the time. The coil was supplied from a 12-volt accumulator, and he estimated that the secondary pressure would be 30,000 volts. The current received by Bodie was a very small intermittent current, and even if the coil had been working at its full capacity, the current would not have been as much as 100 milli-amperes, which was the smallest that would be fatal under any conditions. Mr. Strich had also taken the shock at the same pressure to show that it was harmless. He had not, however, taken quite so much current as Bodie, who had hardened himself to it. The latter had held one terminal of the coil, and allowed the other to spark to his body. There was, added the witness, no risk to life with such a coil; it was merely a matter of endurance.

With regard to Bodie's "electrical training," it was elicited that he entered the service of the National Telephone Co. when between 14 and 15 years old, and remained with them three years before commencing his career as a showman.

On Thursday, the final speeches for the defence and plaintiff were delivered. Mr. Justice Darling, in his summing up, commented upon the fact that the most important piece of electrical apparatus in the case, viz., the "cage of death," had not been brought to court. He was not satisfied with the excuse that it was in Glasgow, and was very heavy. It was not too cumbrous for the defendant to carry it with him all over the country from music-hall to music-hall, and, therefore, this was not a valid excuse. He was glad to notice that an electrical engineer was numbered among the jury, for they would thus be able to put the proper value upon the demonstration given by the defendant. On the face of it, it did not appear that the plaintiff had been taught very much, and if he had been eighteen months learning what apparently any of them could learn in a few hours, when was he going to be taught the many things provided for in the agreement?

As stated above, the jury found that Bodie had not carried out the terms of the agreement, and a verdict of the return to the plaintiff of the £1,000 premium was entered. A stay of execution with the view to an appeal was granted on condition that the amount was paid into court.

Royal Society of Arts.—Among the Papers down for reading before Christmas is one by Mr. T. Thorne Baker on "Photo-Telegraphy," on November 24th.



Electric Traction in Sweden.—The Swedish State Railway Authorities have accepted the combined tender of the Swedish General Electric Co., of Westeras, and Siemens-Schuckert-Werke, of Berlin, for the conversion to electric traction of the section of the North Swedish system between the iron district of Kiruna and the Norwegian frontier. The approval of the Swedish Parliament has yet to be obtained, but it is stated this is now certain. The contract includes two high-speed locomotives for passenger service, twelve goods locomotives, the overhead equipment, and four transformer stations, and amounts to over five million kronen. For supplying the sub-stations, a water-power station will be constructed by the State at a cost of 7·5 million kronen. The total cost of electrification will therefore be about 13 million kronen (approximately £800,000). Very strict conditions have been imposed; if the working costs are higher than those guaranteed the contracting firms must pay the difference; if they are lower, the firms receive two-thirds of the difference.

THE PRESENT STATE OF HEAVY ELECTRICAL ENGINEERING

THE opening meeting of the 1909-1910 session of the Birmingham Local Section of the Institution of Electrical Engineers was held at the Birmingham University on the 3rd inst. A vote of thanks to Dr. Kapp (Birmingham University), the retiring chairman, was proposed by Mr. Chattock (City Electrical Engineer, Birmingham), and was seconded by Mr. Railing (General Electric Co.). Dr. Kapp, in reviewing the work of the past session, mentioned that the area of the local section had been extended to include a radius of fifty miles from Birmingham, with the exception of Nottingham and the Potteries. Dr. Kapp then vacated the chair in favour of Mr. R. K. Morcom (Messrs. Belliss & Morcom), who then proceeded to deliver his inaugural address on the present state of heavy electrical engineering.

In looking back upon the history of the industry from 1900 to the present day, he said that immediately the disturbance caused by the South African War had subsided, the trend of trade had been upward on a steep curve, except that 1904 and 1908 were periods of noticeable depression. The depression of 1904 was, however, partly masked by the demands of the Russo-Japanese War. Both these depressions, particularly the latter, were connected with falling off movements in the principal

1. Copper.
2. Pig Iron.
3. Moderate size generators, per kw.

trades which are large users of electrical power. Again, the expansion in public supply had not been so rapid from 1907 to 1908 as it was from 1906 to 1907, nor was the rate of development of electric tramways maintained.

Board of Trade returns revealed that while our imports of electrical machinery since 1903 have maintained a fairly constant level of about £60,000, our exports have risen from just under half a million to about one and one-third million, with severe falls in 1904 and 1908. From averaging up certain confidential figures from leading firms, Mr. Morcom found that for 1908 68½ per cent. of the output of electrical engineering firms, or a value of about three million pounds, is for home consumption. In comparison with previous years, the exports appeared to have increased faster than the home consumption. There had also been a falling off in the ratio between work for public service to that for private service. According to the report of the Tariff Commission, the home consumption of electrical fittings was between £300,000 and £400,000; out of 20 million lamps used per annum, about seven million were imported.

Turning to the question of prices of raw material, &c., the curve reproduced showed how the prices of copper and iron had increased, while the sale prices of finished machines had been falling. The causes assigned for this fall were threefold. Some put it down to foreign competition either real or feared; others to over-productiveness in the industry; others, again, to depression of general trade. A satisfactory feature is that up-to-date machines are better designed and more reliable than the older; they are better manufactured and much better standardised. A few years ago, to meet the cut prices, some machinery was turned out of inferior design, but the mistake of such a policy has been clearly shown, and his own experience was that our manufacturers now turned out the finest machines in the world at prices far below their true value.

Dealing with the distribution of capital in the industry, Mr. Morcom gave the following table of the capitalisation of various branches of the electrical industry :—

Year.	Large Engineering.	Cables.	Lamps, Fitting, and Wiring.	Traction Accessories.	Instruments and Accumulators.	Foreign Agencies.
1896	1,700,000	1,400,000	880,000	—	450,000	130,000
1902	5,000,000	2,500,000	2,200,000	600,000	900,000	500,000
1908	9,000,000	3,200,000	4,300,000	500,000	1,400,000	500,000

In its infancy the industry suffered from one very bad slump in the early and middle 'eighties, due to the great rush of capital, based on a mistaken idea as to the immediate future. In the year 1882 alone nearly £9,000,000 of capital was raised for electrical enterprises. As a result competition was so keen as to reduce profits to vanishing-point; but improved methods of manufacture and gradual realisation of the over-eager anticipations of the companies gradually steadied the industry into one of increasing prosperity. The progress of electric lighting, which came with the improved design and cheapness of lamps, continued steadily. Electric traction and power found more and more application, and a remunerative business was done during the closing years of the last century by a number of concerns whose names are household words with us.

The beginning of the twentieth century seems to have heralded harder times. The older companies, led on by their excellent trade, increased their capital, and new enterprise was tempted in by the evident prosperity of the business, till to-day we are again in the position that if all our works were full, the demands of our home and export trade would not be enough to take their output. In 1901-2 large factories were built, big extensions were made, and manufacturers were evidently starting on a big campaign of development. In 1903 there were general reports of improving trade and growing business, but here and there a complaint of small profits due to the inauguration of new factories. In 1904, apparently, foreign competition was severely felt, and a heavy fall of prices occurred. In 1905 the general report was that competition was increasing in intensity, though the volume of business was improving. In 1906 came a rise in the price of raw material, in spite of which no corresponding rise occurred in prices. The evidence all points to considerable increase in the volume of trade in 1906 and 1907 in spite of a marked reduction in the increases of municipal expenditure. Reports show that improvements in organisation and design were having their effect in coping with the reduced scale of prices, but towards the end of 1907 the cheerful tone disappeared, and the severe depression of 1908 set in.

It is certain, he continued, that had it not been for increased productivity, the first seven years of this century, excepting 1904, would have been progressively profitable. In fact, 1906-7 were remarkably good years. The introduction of the metallic filament lamp has undoubtedly reduced the requirements in machinery, and it remains for the increased cheapness and efficiency of electric light to stimulate the demand to a pitch when plant requirements shall again assume an upward grade. Cheap electrical power is encouraging further industrial application, and if experience of heavy traction, at present on its trial, is satisfactory, it is only a matter of time before this application is extended. Tramway work is bound to extend with increasing urban population. In shipbuilding more and more work is being done electrically, and the electrical requirements of the ships are growing, while at present the air is full of rumours of the close approach of electrical marine propulsion. All these things give hope that, as the capitalisation which caused the slump in the early 'eighties was justified in the 'nineties, that of the first decade of this century may be justified in the second.

In conclusion, the Chairman said a few words on the education of engineers, and sounded a warning note against specialisation at the expense of a thorough ground work of a mathematical nature.

The proceedings terminated with a vote of thanks to the Chairman for his interesting address, proposed by Mr. Taylor (Birmingham Electric Supply), and seconded by Colonel Lister (Verity's).

STREET LIGHTING IN BOSTON

IN the spring of this year the city of Boston entered into a five-year contract with the Edison Electric Illuminating Co. for street-lighting after a large number of comparative tests between electricity and gas. The gas company made strenuous efforts to obtain the contract, but the city authorities came to the conclusion that electric lighting was better and more economical. According to the *Electrical World*, some 3,500 lamps are involved in the contract, and a feature is the establishment of the 6·6 amp. magnetite arc lamp in the principal streets. The cost of each of these lamps per year of 3,828 hours is fixed at $103.54 (1.75 cents per lamp-hour). These lamps give about three times more candle-power in a given direction than could be secured from the old enclosed 6·7-amp. series arcs formerly used. The contract also included the installation of a number of General Electric (U.S.A.) flame-arc lamps in public squares, &c., and series-tungsten lamps for secondary streets. The total amount of the contract is about $350,000 per year.

In the preliminary tests, the Edison Company was represented by Dr. Louis Bell, of Boston. There were two types of gas lamps offered in competition with the old 500-watt, 6·7-amp., direct-current enclosed arcs, and also with the 6·6-amp., 500-watt magnetite arcs included in the new agreement. These were a high-pressure gas lamp of foreign make and a number of 250-c.p. double-inverted mantle Graetzin street lamps working at the ordinary gas pressure. Incidentally, several tests were made of ordinary Welsbach gas lamps and series tungstens for use on minor thoroughfares.

As the result of the tests on the gas lamps, it was found that only when quite new had they a candle-power approaching the nominal figure of 60 c.p. Generally, the figure averaged about half that. A 60-c.p. (75-watt) tungsten lamp was found to give considerably more light throughout its effective life on the average than a single-mantle Welsbach lamp. Tungsten lamps fall off slightly in candle-power after burning several hundred hours, but in very much less degree than Welsbach lamps (see also ELECTRICAL ENGINEERING, October 21st, 1909, p. 917). Tests on some inverted mantle gas lamps with single burners and metal reflectors showed an average candle-power of 31, and some inverted double-mantle Graetzin lamps gave an average value of 112 c.p., both these values being calculated from readings taken in the street at an angle of 15° below the horizontal. Some 6·7-amp. enclosed-arc lamps gave an average candle-power of 336, and the new 6·7-amp. magnetite arc lamps with ½-in. lower electrodes and opal globes gave an average value of 1,213 c.p. These last readings were taken at an angle of 16° below the horizontal.

Further tests were made to determine the percentage fluctuation in the candle-power of the Graetzin lamps, and these showed that most objectionable fluctuations in the light attended the use of these lamps.

In discussing these results, Dr. Bell pointed out that only one of the Graetzin lamps tested approached the claims that had been made for them by the manufacturers. A very small change in the gas pressure, quality of gas, or air supply lowered the candle-power to a surprising extent. Dr. Bell was unable to get stable burning from a single Graetzin lamp at the Boston gas pressure and a consumption as low as 3·5 cu. ft. per hour, which is the usual stated consumption. The lowest consumption he obtained was 3·9 cu. ft. per hour with steady burning.

With regard to the relative costs of the two systems, along a certain thoroughfare, 16 Graetzin lamps at $560 per year gave a total illumination by test of 1,600 c.p. at 20° from the horizontal, or 2·85 c.p. per year for $1. Five magnetite lamps along a street of about the same length gave a total of about 7,500 c.p. at a cost of $518, as stated above, or 14·6 c.p. per year for $1. The high-pressure gas lamp installed in Boston did not prove a serious rival.

One of the most notable changes was at Copley Square, which was formerly illuminated by seven 500-watt enclosed-arc lamps hung about 19 ft. above the ground. These cost $828 per year, and the illumination is described as having been somewhat scanty. They were replaced by General Electric (U.S.A.) 6·7-amp. D.-C. flame arcs about 50 ft. above the ground, and placed at the apexes of a triangle with a 250-ft. base and 200-ft. sides. The cost of these lamps per year under the new contract is $468.

A test was made in and near Copley Square with a portable photometer upon three flame lamps, two magnetite, and five enclosed lamps. In each case the measurements were taken at an angle of 25° below the horizontal. The flame-arc lamps averaged 2,515 c.p., the magnetites, 965 c.p., and the enclosed arcs, 495 c.p. Ten other magnetite lamps were also tested for candle-power at an angle of approximately 25° below the horizontal, and the average of the readings was 1.150 c.p. Tests were also made upon 12 gas lamps and 9 series tungstens. The tungsten lamps were placed 13·5 ft. above the roadway and were fitted with reflectors. Two types of gas lamps were tested, the Graetzin single-mantle inverted lamp and the Welsbach upright mantle lamp. The Graetzins were placed 15 ft. above the roadway, and the Welsbach mantles were 11 ft. above. The Graetzins were very unsteady, and a variation of 50 per cent. on each side of the normal candle-power was noted while the wind was blowing. The Welsbachs were much more steady. All tests were made at an angle of 25° below the horizontal. The tungsten lamps averaged 59·8 c.p., the Graetzins 79·3 each, and the Welsbachs 61·3. The age of the mantles was not stated in the test record, but from the results it is probable that they were practically new.

The Edison Company is now installing about 600 magnetite lamps per month, distributed about the city, and about 25 positions for flame arcs have been selected. Series-tungsten lamps are being installed at an increasing rate. The standard height for these lamps run from 15 ft. to 18 ft. above the street level.

The Trolley-Bus.—The Metropolitan Tramways, Ltd., who, in conjunction with the Railless Electric Traction Co., have been carrying out experiments with a trolley-bus at Hendon, are asking the consent of the Hendon Council to run the 'bus between Golders Green Tube Railway Station and Hendon, with the possibility of extending it from Hendon to Edgware Road. Before making formal application for this consent, however, the members and officials of the Hendon Council have been invited to a demonstration of the trolley-bus on the trial track at the Tramway Company's Hendon depôt. We described and illustrated the experimental installation in our issue for Sept. 30th, p. 857.

Overhead v. Underground Telephone Wires.—A case is being heard at the West London Police Court, where Mr. E. W. Garrett, one of the magistrates, is acting as arbitrator in a dispute between the Postmaster-General and the Hammersmith Borough Council. The latter claims that underground wires should be installed, whilst the Postmaster-General, in the interests of economy, desires to install overhead wires for certain telephone extensions. The case for the Postmaster-General is that as there are overhead tramway wires in the district already the Borough Council cannot be objecting on æsthetic grounds. Evidence was also called to the effect that overhead telephone and telegraph wires had not been known to depreciate property. The case for the Postmaster-General has been concluded, and the hearing will be continued next week.

Manchester Section, I.E.E.—The following are the arrangements for the session of the Manchester Section of the Institution of Electrical Engineers:—Nov. 16th, "Telephones," by L. E. Wilson; Nov. 30th, "Recent Developments in High Tension Transmission on Overhead Lines," by Prof. E. W. Marchant and E. A. Watson; Dec. 14th, "Notes on Methods and Practice in the German Electrical Industry," by L. J. Lepine and A. R. Stelling; Jan. 11th, "The Testing of Rubber for Electrical Work," by Prof. A. Schwartz; Jan. 25th, "The Generation and Electrical Transmission of Power for Main Marine Propulsion," by W. P. Durtnall; Feb. 8th, "Three-wire Balancers," by A. G. Cooper; Feb. 22nd, "Some Modern Developments in Automatic Switch Gear," by B. Thomas and E. Thomas; Feb. 25th, Annual Dinner; March 8th, "The Short Circuiting of Large Electric Generators, and the Resulting Forces on Armature Windings," by Miles Walker; May 22nd, Annual General Meeting. "Some Properties of Switch and Transformer Oils," by W. Pollard Digby and D. B. Mellis.

The Weston Standard Cell.—At a recent meeting of the Physical Society a Paper was read by Mr. F. E. Smith on cadmium amalgams and the Weston normal cell. Cadmium amalgams may be solid, liquid, or a mixture with a composition depending on the temperature. When a completely liquid amalgam is cooled below the lower transition temperature, the centre of the resulting solid is of high cadmium concentration. Diffusion tends to produce uniformity, and in consequence the E.M.F. of a cell containing the amalgam is unstable for a considerable length of time. When the amalgam is slowly cooled to a temperature a little below the lower transition temperature the difference of concentration between the inner and outer parts of the amalgam need be only small. The diffusion process will be slow and the E.M.F. may remain constant for a very long time. Amalgams of uniform cadmium concentration were obtained by chilling completely liquid amalgams to a temperature of about −50° C. If, however, the temperature of such an amalgam is raised until two phases exist, subsequent cooling will not restore the uniform condition, and an unstable amalgam results. The experiments indicate that a 12·5 per cent. amalgam may be safely used at all temperatures between 12° and 60° C., and a 10 per cent. amalgam at all temperatures between 0° and 51° C. Experiments were made on the temperature coefficients of the anode and cathode limbs of the Weston normal cell, and show that if a difference of temperature of 1° C. exists an error of about 3 parts in 10,000 is introduced.

RECENT DEVELOPMENTS IN HIGH-TENSION SWITCHGEAR

A PAPER on high-tension switchgear was read by Mr. A. G. Collis, of Manchester, on Saturday, Oct. 30th, before the Glasgow Technical College Scientific Society. In the introductory portion of his Paper, the author summarised the practical points to be remembered in the design of switchgear as follows:—(1) Simplicity consistent with adequate protection; (2) ease of operation and inspection; (3) instantaneous response to call of duties; (4) apparatus at high potentials placed in cells so that in case of fire remaining gear will not be affected, and arranged for inspection from exterior and isolation for cleaning, &c.; (5) the use of inflammable material to be avoided as far as possible; (6) sufficient spacing of conductors to avoid risk of short circuits; (7) only low-tension connections and instruments to be on operating board, and these to be traceable at sight; (8) liberality of design to withstand abnormal conditions; and (9) sound earth connections.

He was himself particularly in favour for most purposes of the ironclad type of switchgear, of which he illustrated examples. He thought that when iron constituted the main constructive portion of the board, there was less danger due to this being at the earth potential than with a board of slate, marble, stone, &c., which was liable to contain insulated conducting veins; also in case of fire, iron lent itself to displacements in a better manner than solid stone partitions. For large feeder boards he described another form, taking as an example the St. Andrew's Cross generating station, Glasgow. In this board the whole of the H.T. gear was situated in separate compartments, and operated from a "bench type" control board in the gallery, which gave the attendant full view of the engine. In this case the control was electrical, but direct mechanical control had some advantages. He suggested that, in addition to the electrical instruments, it was an advantage to have on the switch gallery also pressure gauges, &c., which would enable the same man to be in charge of the steam and electrical control.

Mr. Collis considered that many failures of switchgear were due to cheap labour with improved systems which leave the switchboard "not only to protect the plant, but also to stand up against the experimental tests of inexperienced men." He also enlarged upon the iniquities of the lowest tender system, and commented upon the dangerous conditions often introduced as a result of the desire to save capital expenditure, as disclosed in recent Home Office reports. The construction and proper placing of isolating switches was important, and more use should be made in practice of the facilities usually provided for sectionalisation to avoid risk of a complete shut-down, such as that which occurred at Lots Road (see ELECTRICAL ENGINEERING, Vol. IV., pages 524 and 539).

Passing on to matters of detail, he showed illustrations of the construction of several types of oil switches, and spoke in favour of separate wood-lined tanks, with a space between the wood lining and the walls for each pole, and brush type contacts with additional sparking tips. The porcelain insulating sleeves were better of the plain than the reeded pattern, as the latter were more liable to retain dirt. In electrically operated oil switches, he preferred the solenoid to the motor-driven type. Dealing with instruments, a description was given of those on the induction principle, and some notes followed on the proper connection of A.C. wattmeters for reading the total power on unbalanced three-phase systems.

The form of protection most adopted in this country involved the use of reverse-current relays on the generators, and overload relays on the feeders. The plunger relays and differentially wound coils formerly used were now practically obsolete, partly on account of failures under conditions of low power factor and voltage on short circuit, and difficulties with synchronising currents. The form of relay which he favoured for outgoing feeders was a triple-pole time element overload relay, worked by a rotating copper disc between "shaded" pole pieces of a magnet energised from a current transformer. This disc winds up a weight, and its speed of motion is adjusted by a damping magnet, so that the time element can be varied irrespective of the current setting. An illustration of an instantaneous reverse-current relay on the same principle was also shown. There were several ways of connecting up relays and trip coils for protection against overloads. Two overload trips with two current transformers will protect a three-phase system with neutral not earthed, or even one trip coil will be effective, as the current in one phase is equal to the vectorial sum of the currents in the other two. The protection in each leg, however, further advances the degree of safety. When the neutral is earthed three current transformers and two trips should be used with the transformers connected in "Z," *i.e.*, similar to a delta connection with the common transformer reversed. This ensures nearly the same effect of overloads on each phase, as the action is determined by the maximum current in any one phase, rather than the sum of the currents in the different phases. It was, however, a great question whether the neutral should be earthed at all, and exceptional conditions are apt to arise which call for special treatment. In this connection a description was given of Mr. M. B. Field's ring transformer relay, described in ELECTRICAL ENGINEERING of July 1st, 1909, page 599.

The discussion was opened by Mr. A. G. STRATHERN (Weldless Tubes, Ltd.), who deplored the present-day tendency of large companies and corporations to take the lowest tender without adequately considering the risks involved, especially in such matters as the design of H.T. gear.

Mr. JAMES CALDWELL (Messrs. Sayers & Caldwell, consulting electrical engineers, Glasgow) agreed with Mr. Collis as to the essential requirements for the design of H.T. plant, but did not agree as to the means which should be adopted to fulfil these requirements in all cases. They were strongly opposed to the use of reverse-current relays in generator circuits, and preferred hand operation. It appeared to be impossible to get a reverse-current relay, which would cut out a machine equally well with a failing field or faulty winding. Instrument transformers, as usually designed, were too light, and were often the cause of "shut-downs." He was of opinion that wood, wherever used on H.T. gear, was a source of danger. In one test recently carried out with E.H.T. gear at 10,000 volts, an oil switch burned out, and it was found that the wooden lining had punctured and carbonised.

Mr. J. MENMUIR (Messrs. Kelvin & James White, Ltd., Glasgow) wanted to know why the old ribbed insulator was being discarded?

Mr. S. RICHARDS (Messrs. S. & P. Coats, Ltd., Glasgow) also asked a few questions, inquiring among them why, when it was not convenient to apply continuous current to relays, alternating current could not be used?

Mr. COLLIS, in his reply, said that he agreed that reverse-current relays could not be made to act satisfactorily on both a failing field and faulty winding. Stoppages due to the latter trouble were, however, very few, and usually gave sufficient warning of their imminence. The real use of the R.C. relay was to prevent extensive damage due to imperfect handling and bad synchronising. Relays to act on a failing field with precision certainly can always be easily designed if the characteristic of the generators is obtained. With reference to faulty instrument transformers, he described a new current transformer, which consisted of a straight rod primary, surrounded by a cylindrical insulator, this in turn being surrounded by an iron case in the form of a ring, round which the secondary coils were wound. As he had already pointed out in the Paper, ribbed insulators were being discarded, as it was found that dirt and dust would collect in the grooves, and that the long leakage path soon becomes a short one in practice. A.C. trip coils could be used, but they could not be arranged to give anything like so fine an adjustment as D.C. coils.

Faraday House Old Students' Association.—A smoking concert and an "At Home" will be held at Faraday House, London, W.C., on Friday, December 3rd, from 8 to 11 p.m. Mr. Alexander Russell, M.A., B.Sc., the new Principal of Faraday House, will take the chair at the concert.

Electro Harmonic Society.—The date of the next concert (ladies' night) is Monday next, November 15th, and not upon the usual Friday evening. The concert will be held in the King's Hall, Holborn Restaurant, London, at 8 p.m.

Life Tests on Metal Filament Lamps.—The A.E.G.-Zeitung for November contains a report by Dr. L. Bloch on some life tests on five A.E.G. 110-volt 25-Hefn. c.p. metal filament lamps. Of the five, one burnt out at 6,800 hours, and a second at 8,700 hours, while the other three lasted over 10,000 hours, running continuously. The average candle-power rose from 26 to 27·2 after 100 hours, and then fell gradually, the reduction being 20 per cent. after 6,700 hours. After 10,000 hours the candle-power had fallen 25 per cent., and the watts per (Hefn.) candle were 1·6. At the commencement the consumption was 1·2 watts per candle, rising gradually to 1·4 at 6,000 hours.

Automatic Sanding Gear for Tramcars.—A sanding gear which is brought into action automatically when the controller handle is moved to the short-circuit braking position has been used for some considerable time on the Dresden and Coblenz tramways. In a pamphlet issued by the Allgemeine Elektricitäts-Ges. two forms are described. In one, the slide of the sand box is drawn mechanically by a lever connected to a crank on the end of the controller spindle, and in the other the slide is drawn by a plunger and solenoid, the circuit of the latter being closed when the controller is in the braking position. A 10-ton car, running at 12½ m.p.h., can be pulled up in a distance of 16 ft. on clean, dry rails, and in 24 ft. on greasy rails. Without the gear the distance covered before stopping might be as much as 80 ft. The gear is stated to have worked very satisfactorily, and to have prevented many accidents.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Pubiished Nov. 4th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

19,263/08. **Insulation of Windings.** A. J. BOULT (*Felten & Guilleaume-Lahmeyerwerke Akt.-Ges.*). Transformer coils and armature windings comprising bare copper wires or bars separated by small strips of insulating material, are dipped into a bath of rubber solution or of acetyl cellulose. The armature or coil is then subjected to a vulcanising treatment to harden the insulating mass. Four claims.

21,779/08. **Limit Switch.** G. WILKINSON. In lighting installations supplied on the contract demand principle, a resistance wire is connected in the main circuit, and this, when the current exceeds the prearranged maximum, causes the circuit to be broken by reason of its expansion. An intermittent making and breaking of the circuit goes on until the current is reduced. To avoid the error due to atmospheric temperature variations, the parts of the device are made of metal having the same temperature coefficient as the wire, and are so shaped that relative movements due to atmospheric temperature variations are eliminated. A condenser or resistance is connected across the contacts. Two claims, five figures.

22,159/08. **Compensating Speed Variation of Shunt Motors.** W. STANSFIELD and J. J. HATT. To obviate the rise in speed of shunt motors due to the heating of the field coils, two opposing field windings are employed. The weaker is connected directly across the supply mains, and the stronger is placed in series with a resistance having a negligible temperature coefficient. As an alternative, the weaker winding may be connected in parallel with the resistance. The difference between the ampere-turns of the two windings remains constant for all temperatures. Three claims, four figures.

22,880/08. **Marine Steering Gear.** B. PARKER-HAIGH. In an electrically-driven marine steering gear, the motor is kept running continuously. Power is transmitted to the gearing through two friction clutches on extensions of the motor shaft, one for each direction of motion of the rudder. The clutches are operated by solenoids controlled by a handwheel on the bridge. The motor is provided with a flywheel, and is arranged to have a considerable drop in speed between no-load and full-load. Three claims, four figures

23,118/08. **Battery Charging Switch.** NALDER BROS. & THOMPSON, LTD., and F. H. NALDER. In a modified form of the well-known automatic switch made by this firm, the high and low resistance coils are wound on one bobbin, and the pivoted bar of iron to which is attached the contact pins, passes through this bobbin. A permanent magnet fixed below the bar causes it to swing according to its polarity, and make or break the charging circuit. The permanent magnet may have a series coil to strengthen it. Two claims, seven figures.

25,721/08. **Motor Controller.** A. WEST. In order to obtain a quick break in a drum controller, independent of the movement of the handle, the drum consists of a series of discs which pass through stationary copper clips bearing on both sides of the discs. The discs are cut away where contact is not required, and where the segment leaves the clip, a small spring knife switch is fixed in the plane of the disc. These auxiliary switches give a quick break and obviate the necessity for a magnetic blow-out. Four claims, three figures.

15,270/09. **Time-limit Device for Circuit Breakers.** THE ELECTRIC & ORDNANCE ACCESSORIES CO., LTD., J. R. GARNER, and N. COLLINS. This is the time-limit device for attaching to circuit breakers, described in ELECTRICAL ENGINEERING, July 15th, 1909, page 648. Six claims, six figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: MOUNT, 22,454/08; DUSCHNITZ [Converging carbon lamps] 11,578-9/09.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: TAYLOR [Storing and distributing in A.-C. systems] 22,044/08; PECK [A.-C. transformer distribution system] 23,064/08.

Dynamos, Motors, & Transformers: STANSFIELD and HATT [Pressure regulation of variable speed generators] 22,500/08; STEVENS [Portable electrically-driven pumps] 23,328/08; MALLINSON [Rotary pumps] 4,928/09; BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts-Ges.*) [Control of polyphase motors] 17,370/09.

Electric Ignition: WILLIAMS [Sparking-plug] 2,984/09.

Electrometallurgy & Electrochemistry: BASSET [Batteries] 22,236/08; BILLITER [Electrolysis] 24,594/08.

Incandescent Lamps: HEINRICH [Manufacture of metal filaments] 7,092/09; FARBER, 7,913/09.

Instruments & Meters: HOOKHAM and HOLDEN [Prepayment meter] 3,217/09.

Switchgear, Fuses, & Fittings: MYGATT [Lamp-shades] 17,440/08 and 8,183/09; RAWLINGS [Fixing lamp-brackets] 23,053/08; SWEETSER [Switches] 27,213/08; WILLIAMSON [Portable lamp fitting] 3,836/09.

Telephony & Telegraphy: BURSTYN [Wireless telegraphy] 15,354/08; CONNER [Signalling key] 4,270/09; SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*) [Telephone exchanges] 6,281/09, 14,239/09, and 18,456/09; GRAHAM [Telephony] 21,002/09.

Traction: ROBINSON, 22,227/08, and 9,623/09; MURRAY [Tramway conduit points] 22,314/08; BRITISH INSULATED & HELSBY CABLES, LTD., and ASTLEY [Overhead gear] 22,413/08; PARKER [Signalling] 28,000/08; GRESHAM [Air-brakes] 4,870/09; PRICE [Block signalling] 6,289/09; FISHER [Car indicator] 6,818/09; DONALDSON and PORTER [Signalling] 7,415/09; SOC. CH. LEGRAND ET CIE [Signalling] 8,168/09; RUSSELL and LORD [Section insulator] 11,210/09.

Miscellaneous: VENNER [Illuminated signs] 22,319/08; HEIDECKE and LELLAU [Mining pumps] 24,527/08; KERR [Coal-cutters] 24,755/08; ALBERY [Alarm device] 2,903/09.

The following Specifications are open to Inspec tion at the Paten Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: STERN [A.-C. motor windings] 23,553/09; LIPPELT [Machines] 23,756/09.

Electrochemistry: PATTERSON and HOPPER [Batteries] 11,155/09.

Meters: BECKER, 23,404/09.

Switchgear, &c.: MURRAY [Cut-outs] 23,227/09; "WATT" INSTALLATIONEN FÜR STARK-UND SCHWACHSTROM CARL SCHULZ [Push-button switches] 23,526/09; MONNIER [Distributing box] 23,937/09.

Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

21,553 of Nov. 13th, 1895. **Rail Joint.** G. FLETT and DICK, KERR, & Co. One or both fish-plates are extended upwards to replace part of the rail head which is cut away.

21,569 of Nov. 13th, 1895. **Railway Signalling.** W. R. SYKES. In a block-signalling system, the mechanically-operated signal levers are electrically interlocked with the block instruments. Before a "line clear" signal can be given, the train must pass over a treadle and thereby complete an electric circuit.

21,831 of Nov. 16th, 1895. **Railway Signalling.** E. TYER. This patent covers an electrically-operated instrument for issuing tablets or staffs for controlling the traffic on single-line railways.

21,924 of Nov. 18th, 1895. **A.-C. Meter.** G. HUMMEL. The field magnet of a Ferraris motor meter is provided with closed circuit coils in addition to the main series winding, or a non-inductive winding is placed in shunt across the main winding. An adjustable shunt inductance is also used, and a small piece of iron is fixed on the copper disc to prevent rotation due to the current through this inductance.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: F. HARRISON [Mercury-vapour lamps] 14,660/05; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Vapour rectifiers] 14,715/05.

Distributing Systems, &c.: P. CORIDORI [H.T. cables insulated with compressed air] 14,889-9A/05.

Dynamos, &c.: R. B. RANSFORD (*Deutsche Elektrizitäts-Werke, Garbe, Lahmeyer & Co.*) [Pole shoes] 16,117/02; J. BROCKIE [Train-lighting alternator] 14,938/05; H. V. JAMES [Variable speed motors] 15,002/05; ALLGEMEINE ELEKTRICITÄTS-GES. [Control of A.-C. commutator motors] 15,067/05.

Electric Ignition: D. E. BROWN [Induction coils] 15,121/05.

Electrometallurgy and Electrochemistry: O. IMRAY (*Farbwerke vorm. Meister, Lucius, & Brüning*) [Production of chromic acid] 15,724/98; P. SPENCE & SONS [Production of titanium chloride] 16,238/02; T. PARKER [Furnaces] 14,884/05.

Incandescent Lamps: J. CRAWFORD [Flashing carbon filaments in solutions containing boron and silicon] 14,898/05.

Instruments: W. HIBBERT [Magnetometer] 15,821/03.

Storage Batteries: C. VELLINO [Casting plates] 15,963/02.

Switchgear, &c.: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Drum controller with blow-out magnets] 16,260/04.

Telephony and Telegraphy: H. H. LAKE (*N. Tesla*) [Wireless apparatus] 14,579/01; B. BRANDER [Central battery exchange system] 16,038A/04; A. GENTILI [Transmitting key] 14,770/05; W. R. SINE and J. S. ROSENTAAL [Telephone shell] 14,808/05.

Traction: H. H. LAKE (*General Electric Co., U.S.A.*) [Protected third rails] 16,062/02; R. D. WHITING [Air-brakes] 14,818/05.

SUMMARY

On Wednesday of last week, Mr. L. Brennan gave a demonstration of his full-size mono-rail vehicle, in which the centre of gravity is high above the point of support and stability is obtained by gyrostatic mechanism. The gyrostats are electrically driven, and the precession is automatically accelerated by compressed-air gear to produce the necessary balancing effect. In the present car, power for the main traction motors and the auxiliary machinery is obtained from two petrol-electric sets on the car. It is stated that heavy vehicles of large dimensions can be run at very high speeds, and sharp curves negotiated without fear of lateral oscillations. (Page 977.)

In our issue of October 28th we described the new 6,000-kw. generating set at the Stuart Street station of the Manchester Corporation. This week we publish an illustrated article on other alterations and additions that have been made in the station. These include the entire rearrangement of the H.T. switchgear, the erection of four boilers of the B. & W. marine type, the installation of a speed recorder for giving a continuous record of the speed of the engines, and the addition of a battery for excitation and the D.C. auxiliaries. (Page 979.)

In the latest pattern of equipment for driving rotary presses on the Holmes-Clatworthy system, the two motors are controlled by a motor-driven rheostat. The rheostat motor is controlled by solenoids set in operation by push-button switches on the press. Means for hand operation is also provided. (Page 981.)

As the result of some tests to determine the coefficient of friction of brake blocks under different conditions, Prof. E. Wilson has found that the effect of water on the blocks is to reduce the coefficient in the case of non-metallic blocks to a dangerous degree. Cast-iron blocks showed little variation. Tests were made at different speeds and with various specific loads. (Page 982.)

The Board of Trade are addressing a letter to tramway authorities throughout the country, calling their attention to the necessity for care in testing the signal device employed to indicate the becoming "alive" of a trolley standard, and recommending the adoption of an audible signal rather than the usual red lamp. (Page 982.)

Only very few electric cars are on view at the Motor Car Exhibition now being held at Olympia, but there is an excellent display of electrical accessories, including ignition apparatus, among which are exemplified a number of dual ignition systems and self-starting devices for use with magnetos. Electric lighting outfits, lamps, electric horns, electrically-heated vulcanisers, and various other applications of electricity to the needs of motorists are also exhibited. (Page 983.)

Digitized by Google

In his presidential address to the Institution of Electrical Engineers, Dr. G. Kapp reviewed the present state of some of the branches of the electrical industry. He described some new machines, including a high-speed asynchronous generator for low frequencies, a modified Winter-Eichberg commutator motor with a shunt characteristic, and an alternator in which a large pressure drop is obtained without endangering the safety of the machine on short-circuit. The various methods of cooling large transformers were discussed, and some recently invented devices for protecting H.-T. systems were described. Referring to electric traction, Dr. Kapp expressed the opinion that single-phase traction would be the system to be adopted in the future, and gave some interesting information with regard to the application of the three-phase system in Italy. The development of the electric furnace, and the application of electricity to the driving of rolling-mills, the fixation of atmospheric nitrogen, and the promotion of the growth of plants, were also dealt with. (Page 985.)

The dinner of the Birmingham Section of the Institution of Electrical Engineers was held on Friday. (Page 986.)

At a recent meeting of the Institution of Civil Engineers, three Papers were read relating to actual experiences with electric traction on full-sized railways. In one of these Messrs. J. Dalziel and J. Sayers described in considerable detail the equipment on the single-phase system of the Heysham-Morecambe branch of the Midland Railway, and stated that the weight of the single-phase train was only a very small percentage greater than that of a corresponding direct-current train, and that the energy consumption was appreciably less. The second Paper, by Mr. J. Shaw, gives striking figures showing the saving due to the introduction of electric traction on the Mersey Railway, and the last, which is by Dr. C. A. Harrison, gives working results of the electrified lines of the North Eastern Railway in the neighbourhood of Newcastle. (Page 987.)

At the inaugural meeting of the Dublin Local Section of the Institution of Electrical Engineers, Prof. W. Brown gave a discourse on the magnetic testing of iron. (Page 988.)

A memorial bust of the late Dr. John Hopkinson, executed by Mr. H. Thornycroft, has been presented to the Institution of Electrical Engineers by Mrs. John Hopkinson. The presentation was made on Thursday last by Prof. Bertram Hopkinson on behalf of his mother. (Page 988.)

The offices and library of the Institution of Electrical Engineers will not be moved into the new building on the Victoria Embankment until June, and the first meeting to be held there will be the inaugural meeting of the next session (November, 1910). The reconstruction of the lecture hall is now in progress. (Page 988.)

A letter from Mr. W. B. Woodhouse (Chief Engineer to the Yorkshire Electric Power Co.) calls attention to the lack of unanimity in the Committee of the Bradford Engineering Society, which recently issued a report on the question of electric textile factory driving. An anonymous correspondent criticises the procedure at meetings of the Institution of Civil Engineers. (Page 989.)

Marylebone Borough Council propose to lay an extensive system of mains for supplying public lighting in districts where no electric supply is now given. These mains will serve the double purpose of public lighting and supplying consumers (mostly small installations) who have hitherto been out of reach. A loan of £24,000 is to be applied for.—The Board of Trade refuse to force the Aberdeen Suburban Tramways Co. to accept the award of Mr. Patchell as to the charge to be made by the Corporation for electrical energy.—A dispute has arisen between the Dublin United Tramways Co. and the Dublin Corporation as to the rent for wayleaves.—An agreement is possible between the City Corporation and the County of London Co. as to the route for connecting up the Wandsworth and City Road power-houses.—Tramway employees in Newcastle-on-Tyne threaten to strike.—A new bridge, to carry tramways, is to be built over the Thames. (Page 989.)

Keighley Corporation propose to borrow £21,000; Lowestoft, £1,182; Pembroke, 8,000; and Wednesbury, £1,750. New mains are to be laid at Southend at a cost of £1,000. Large expenditures are contemplated upon electrical schemes in South Africa. (Page 990.)

An inquest was held last week concerning the death of a guard who was found dead in the driver's cab of an electric train on the Metropolitan District Railway. Medical evidence attributed death to electric shock, and the inquest was adjourned for expert evidence. (Page 991.)

The accounts of Messrs. Richardsons, Westgarth & Co. for the year to August 25th show a loss of £17,326. The Castner-Kellner Alkali Co. pay a dividend of 14 per cent. for the past year. (Page 992.)

An exhibition of electrical domestic accessories is being held at Wimbledon. A new apparatus to be seen is an electric water-heater on the "Bastian" quartz principle. (Page 993.)

A short article mentions the latest developments of the Venner sign and the new works of the Credenda Conduits Co. (Page 993.)

Among the specifications published by the Patent Office on Thursday last was one by W. A. Stevens, for a portable pumping plant, comprising a petrol-electric generating set on a vehicle, a trailing cable, and an electrically-driven pump on a separate trailer. An improved electrolytic vat in which the diaphragm is horizontal and the products of electrolysis are separated by the difference in specific gravity in the layers of the electrolyte, is described by Dr. J. Billiter. W. Freinrich describes a binding agent for forming filaments of tungsten, consisting of a mixture of sulphur and phosphorus. By starting up an A.-C. commutator motor as an asynchronous induction machine, the British Thomson-Houston Co. are enabled to design large single-phase motors with a wide speed variation near synchronism. A method of preventing double connection and consequent overhearing on telephone circuits is protected by Siemens Bros. & Co. In spite of opposition, a patent has been granted to C. Notbohm for a heat accumulator, and the opposition to the patent by G. Michaud and E. Delasson for filaments of refractory oxides has also been unsuccessful. (Page 994.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, NOVEMBER 18th.

Illuminating Engineering Society.

8 p.m. At the Royal Society of Arts. Presidential Address, by Prof. Silvanus P. Thompson, F.R.S.

MONDAY, NOVEMBER 22nd.

Institution of Electrical Engineers: Newcastle Section.

8 p.m. At Armstrong College. Inaugural Address by Prof. H. Stroud.

TUESDAY, NOVEMBER 23rd.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. At the Municipal School of Technology. "The Testing of Electrical Machinery," by R. F. Blackmore and V. W. Newman.

Institution of Civil Engineers.

8 p.m. Further discussion on the three Papers dealing with electric traction read on November 9th.

WEDNESDAY, NOVEMBER 24th.

Royal Society of Arts.

8 p.m. "Photo-Telegraphy," by T. Thorne-Baker.

THURSDAY, NOVEMBER 25th.

Institution of Electrical Engineers.

8 p.m. At 25 Great George Street, London. "The Present Aspects of Electric Lighting," by H. W. Handcock and A. H. Dykes.

THE BRENNAN MONO-RAIL TRACTION SYSTEM

IT is now somewhat more than two years ago that Mr. Louis Brennan exhibited a model mono-rail vehicle, in which the centre of gravity was well above the point of support, and stability was obtained by gyrostatic mechanism. Since then Mr. Brennan has been carrying out investigations and experiments at the Brennan Torpedo Factory at Gillingham, and has nearly completed a full-size vehicle on the same principle. A demonstration of this vehicle was to have been given next month, but, having heard on Tuesday of last week that a full-size gyrostatic mono-rail vehicle 15 ft. long was to be exhibited on the following day in Berlin, Mr. Brennan decided to give a hurried demonstration last Wednesday of his own car in an unfinished state, at which we had the pleasure of being present.

As yet, no particulars of the German car are to hand, but it is announced to be the invention of Herr August Scherl, the proprietor of a Berlin newspaper, the *Lokal Anzeiger*, and the author of the book "Ein Neues Schnellbahnsystem," reviewed in ELECTRICAL ENGINEERING, August 5th, 1909, page 711. The car is said to have been developed in Herr Scherl's own workshops, and to embody considerable improvements on the model car exhibited by Brennan in 1907. Mr. Brennan, however, informs us that his master-patent, No. 27,212, of 1903, which has been taken out in thirteen different countries, including Germany, is so broad in its claims that it covers the use of gyroscopes to make any unstable body stable, whether on land, at sea, or in the air. Consequently, he considers that the Scherl car must be an infringement of his patent. Besides this patent, Mr. Brennan has applied for five others connected with the same subject. It may be mentioned that Mr. Brennan has received considerable financial assistance from the British and Indian Governments and from the Government of Kashmir, a total amount of £15,000 having been subscribed from these sources for the purpose of developing the system.

The car, illustrated in Figs. 1 and 3, is 40 ft. long,

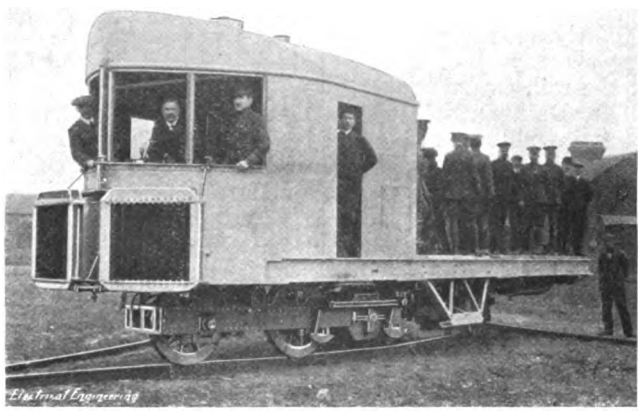

FIG. 1.—THE BRENNAN MONO-RAIL VEHICLE.
(Mr. Brennan in centre of cab.)

10 ft. wide, and 13 ft. high, and has a dead weight of 20 tons. It is capable of carrying a load of over 15 tons at a speed of 25 miles per hour on the level, or at from 3 to 5 miles per hour up an incline of 1 in 13. The centre of gravity of the car is high above the rail level, and a stable condition is obtained by the use of two gyroscopes mounted in the car as indicated in Fig. 2, with the axes horizontal and transverse to the direction of motion of the car. The flywheels *A* of the gyroscopes are rotated at a speed of 3,000 r.p.m. in opposite directions, and each is driven by two 4 h.p. continuous-current motors *B*, one on either side of the wheel. To eliminate air friction, flywheels and motors are run in metal casings, in which the air pressure is maintained at one-sixtieth of an atmosphere, or practically a vacuum. The casings *C* are pivotted at top and bottom so as to be capable of movement around a vertical axis, and the gyrostatic influence of the whole, when the flywheels are in motion, is such that the car is slightly tilted about the horizontal rail as an axis in such a way as to bring it into equilibrium with any forces tending to upset it.

Before describing the equipment in detail, it will be as well to explain briefly how it is that the gyroscopes can be caused to maintain the stability.

Considering the right-hand wheel in Fig. 2 spinning about the axis *XX*, suppose that a couple *PP* is applied,

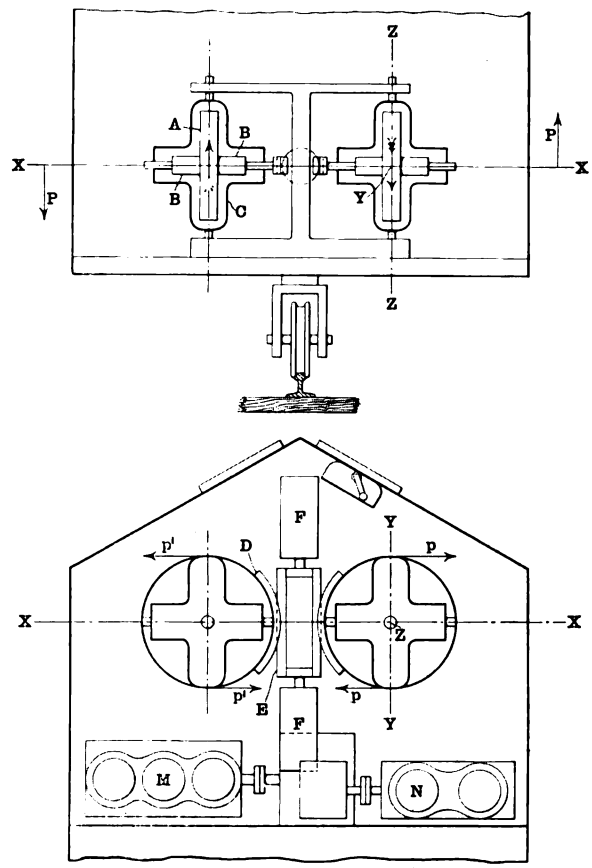

FIG. 2.—DIAGRAMMATIC PLAN AND SECTION OF CAB OF BRENNAN VEHICLE TO ILLUSTRATE THE WORKING OF STABILITY MECHANISM.

tending to turn it about an axis *YY*. If free to move, the wheel, on account of the gyrostatic effect, will not turn about the axis *YY*, but about the axis *ZZ* in the direction indicated by the arrows *pp*. This is at right-angles both to the axis of spin and to the axis of the acting couple. Again, if the same couple is applied to the left-hand wheel rotating in the opposite direction, it will turn about the axis *ZZ* in the direction indicated by the arrows *p'p'*. The speed of rotation about the axis *ZZ* is known as the rate of precession, and is dependent upon the magnitude of the couple *PP*. Now if two such gyroscopes are mounted, as shown, on an unstable vehicle, and the load is shifted so that a couple tending to upset the equilibrium of the vehicle is produced, the gyroscopes would precess and offer an opposing couple. This couple alone would only cause the vehicle to overturn more slowly than it would do if the gyroscopes were not present. By artificially increasing this rate of precession, however, a stronger deflecting couple can be withstood, or if the latter remains constant, there will be an unbalanced couple tending to turn the gyroscopes about the horizontal

Digitized by Google

axis *YY*, in a direction opposed to that of the original deflecting couple.

In the Brennan full-size car, the precession of the gyroscopes is accelerated by a compressed air gear, and the unbalanced couple produced deflects the car in the direction opposite to that produced by the shifting load or any other cause until the centre of gravity is again immediately over the rail. When the latter position is reached the momentum of the car causes it to overstep the mark, and an opposite horizontal couple is applied to the gyroscopes, with the result that the flywheels are swung round their vertical axes to the normal position. The reason why two gyroscopes are employed will be apparent from what follows.

The compressed air gear takes the place of the friction device employed for a similar purpose in the model of 1907, and comprises two air cylinders *FF*, the pistons of which move the racks *E* backwards and forwards. Any precessional movement of the gyroscopes opens the inlet valves of the cylinders, and the pistons move the racks and accelerate the precession. The racks engage with toothed quadrants *D* on the horizontal bearing rings of the gyroscopes. The motion of either wheel about the axis *ZZ* is transmitted to the other, but the direction of motion is

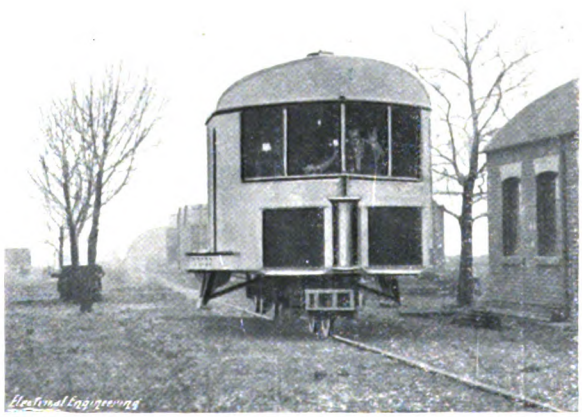

FIG. 3.—END VIEW OF BRENNAN MONO-RAIL VEHICLE.

reversed, one moving clockwise, and the other counter clockwise, or *vice versâ*. In this way the tendency of either gyroscope to check the free motion of the car round a curve is neutralised by the other. If only one gyroscope were used there would be an unbalanced force tending to prevent any change in the direction of longitudinal motion. Besides compensating for the effect of shifting loads, the gyroscopes are made to neutralise automatically the effects of centrifugal force when the car is rounding curves. The action is just the same as when the vehicle is subject to any couple tending to turn it about the rail. Equilibrium is established by tilting the car so as to give it the theoretical super-elevation required for the given speed and the radius of the curve on which the car is running. The effects of wind pressure are also compensated for, and the present vehicle is under sufficient gyrostatic influence to withstand a side wind pressure of 40 lb. per square foot. To demonstrate the rapid action of the gyroscopes, a weight of two tons has been rolled off the side of the vehicle, which has recovered its balance immediately. Very little power is required to keep the flywheels running when once they have been brought up to full speed, and, should the current be cut off, the kinetic energy stored in them can keep them revolving at a speed sufficient to maintain the stability of the car for at least three-quarters of an hour.

The present vehicle has two bogie trucks. Each truck has two double-flanged wheels, one of which is driven through single reduction gear and a coupling bar by a 50 h.p. continuous-current traction motor. By driving through coupling bars it is possible to have the motors entirely spring suspended. The motors are supplied with power at 500 volts from an 80 h.p. petrol-electric set *M*, and there is a 20 h.p. set, *N*, for supplying power to the four gyroscope motors, the vacuum pump, and the air compressor. These sets comprise Wolsley marine type engines and Siemens dynamos. Connections are provided, however, by means of which either set can be used for both purposes, and, indeed, the demonstrations on Wednesday were given without the use of the large set, which was under repair. The small set ran the gyroscope motors and the auxiliaries, and also supplied sufficient power to the main motors to enable the car to be run at a fair speed.

The gyroscope flywheels, which are constructed of a special high-class steel, are about 3 ft. 6 in. in diameter, and weigh $\frac{3}{4}$ ton each. The gyrostatic influence of these, when running at 3,000 r.p.m., Mr. Brennan informs us, is much greater than is really necessary for the present vehicle. The motors as well as the flywheels run in a vacuum, and keep cooler than they do when air is admitted, although all the heat generated must be dissipated either by conduction through the shaft or by radiation to the casings. Although the vacuum pump is always kept going, the pressure does not increase appreciably after several hours, as by careful vanishing the cases have been rendered practically airtight. The bearings are cooled by forced oil lubrication, the used oil being circulated through copper coils to cool it before readmission. By employing interpole motors running at a considerably higher speed than 3,000 r.p.m., Mr. Brennan hopes to reduce both the size and weight of the gyroscopes.

The track at Gillingham comprises a circle $\frac{1}{8}$ mile in circumference, and a straight piece $\frac{1}{4}$ mile long. A 70 lb.-per-yard rail of Vignole section, with a surface rolled to a 2 in. radius is used, and this is fixed by spikes on 3 ft. 6 in. sleepers, spaced about 3 ft. apart on ordinary "made" ground. There are various curves, and, in two cases, reverse curves of as small a radius of 35 ft. are present. The points are particularly simple, as there are no tongues, but merely two short portions of rail, which are shifted parallel to the rail.

Mr. Brennan sees a great future for mono-rail railways in undeveloped countries, such as Australia, as the track is inexpensive and easily laid, and extremely heavy vehicles of large dimensions can be run at high speeds without fear of the lateral oscillations experienced on double track railways. Locomotives could be employed to haul a number of trucks, but as each truck must in any case have a gyrostatic stability mechanism, it is probable that a multiple-unit system would be more suitable. In the latter case the weight of the trucks would act as useful adhesion weight, and heavy gradients could be negotiated. Another possible application of the system is for street traction.

In conclusion, it may be mentioned that the Brennan system is entirely different from the apparatus devised by Dr. Otto Schlick to prevent the rolling of ships. In the latter, a gyroscope fitted in the ship is rotated in a horizontal plane with its spindle vertical, the effect being to increase the natural period of oscillation of the ship, so that it does not respond to the successive rocking efforts of the waves. When rolling, the spindle inclines from the vertical in a plane parallel to the length of the ship, and thus produces a balancing couple at right-angles to this. In this case, the gyroscope is employed to prevent a stable body oscillating, and not to render an unstable body stable.

RECENT EXTENSIONS AT THE STUART STREET ELECTRICITY WORKS, MANCHESTER

IN our issue of October 28th, we described the new 6,000-kw. turbine set which has recently been put into commission at the Stuart Street station of the Manchester Electricity Department, and has shown exceptionally good steam consumptions on test. A number of other alterations and additions have been made in the station. First and foremost, the entire H.T. switchgear has been rearranged. During the past few years great improvement has been made generally in the general lay-out of switchgear in large power-houses, and at Stuart Street the older portions have been replaced by Ferranti, Ltd., and the Westinghouse Co., so that the high-tension switchgear system embodies the best and most modern ideas for safe and efficient working.

It will be remembered that there are now two 6,000-kw. generating sets. The E.H.T. switchgear for these turbo-generators, which has been supplied and erected by Messrs. Ferranti, Ltd., is situated in the basement opposite the units, and in a room or cellar solely devoted to this gear, which is thus isolated from all other switchgear on the station. This switch-room contains two distinct blocks of brick cells parallel to each other, and running the length of the room with ample passages all round.

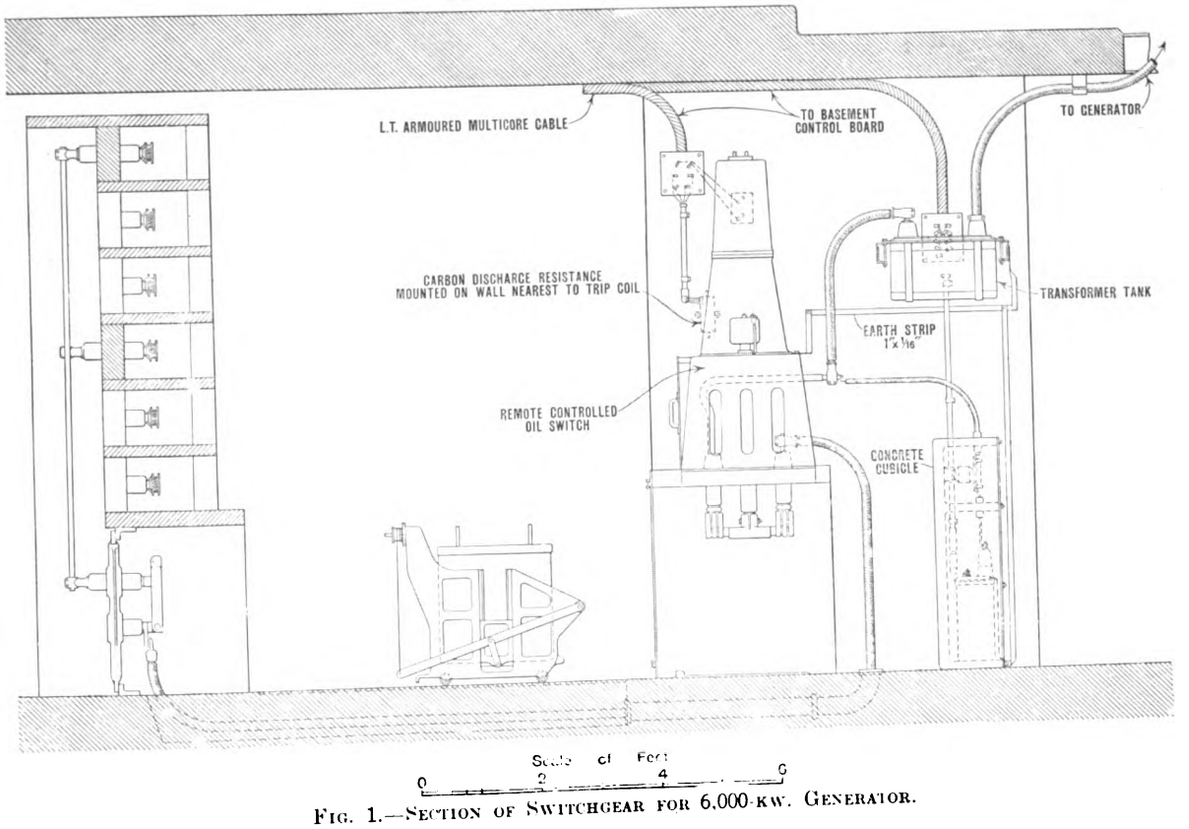

FIG. 1.—SECTION OF SWITCHGEAR FOR 6,000-KW. GENERATOR.

The first block contains the electrically-operated remote control oil circuit-breakers and current and potential transformers, the dividing walls between the cells being exceptionally substantial; while the second contains only the duplicate sets of 'bus-bars and isolating switches, the brickwork being the usual 4½-in. walls and concrete slabs. The gear installed at present controls two generators and two group-feeders, the feeders conveying power to feeder blocks in another part of the station. Provision is made for one spare generator, and there is ample room for future extensions. Fig. 1 is a section of the H.-T. cells. The cables from the generators enter the switch-cells at the top, and are taken to oil-cooled current transformers, one on each phase, contained in one tank; from the transformers they are taken to the electrically-operated oil switches, and from them through chases in the floor to the isolating selector switches in the 'bus-bar block, and through the switches to either set of 'bus-bars.

Tappings are taken off at the oil circuit-breaker terminals to three-phase delta-connected potential transformers which, together with their fuses, are contained in concrete cubicles standing on the floor below the current transformers.

The switches are in their general design similar to Messrs. Ferranti's latest patterns of remote-control switches employed elsewhere with much success. The solenoid which works the switch is formed of two coils, housed in a casting at the top, and the plunger is formed of two thin concentric slotted iron tubes split longitudinally, and with an air space between them and a thin disc inserted at the upper end. This arrangement ensures rapid magnetisation of the iron and instantaneous operation, which is most important for proper paralleling of large sets at the moment of synchronism, although it is usually difficult of attainment in heavy switches. The plunger has a travel of about 12 in., and the weight of the contact pieces attached to it is partly relieved by a pair of long tension-springs, which assist the plunger when the switch is closing. A pair of leaf springs act as buffers when the switch opens. The attachment of the fixed contacts is flexible. The gear for holding down the switch and for tripping it without undue shock (by the use of a balance-weight with considerable inertia) is also the same as in the firm's previous designs, and the chief modification is in a general lightening of the moving parts, and the use of a pendulum and escapement in connection with the controller, instead of the former oil dashpot, for giving the necessary definite time interval.

From each oil switch two sets of armoured multicore cables are run to the control board, the one of seven cores connecting the current and potential transformers to the instruments, the other of six cores connecting the operating and tripping solenoids and signal controller to the main controller push-buttons and signal lamps.

The control panels are on a main gallery running the length of the station, and form part of a board controlling other generators and feeders.

Each panel is provided with the following apparatus:—At top, one illuminating lamp and bracket; three A.-C. induction type ammeters, one overload relay, single pole, with duplicate plug contacts and indicating lamp; synchroniser plug contacts; controller and push-buttons for electrically-operated oil circuit-breaker; red and green signal lamps; tumbler switch for trip circuit; indicating wattmeter; idle current ammeter; three instantaneous relays for the Merz-Price protective device; and one integrating watt-hour meter for unbalanced loads.

Digitized by Google

The overload relay is normally shunted when on load, and is only in use at the moment of synchronising, the indicating lamp in connection with it being lit by withdrawing the plug which normally shunts the relay and inserting it in the lamp-lighting sockets.

The synchroniser gear consists of the usual rotary synchroniser, with synchroniser lamp and a duplicate set of 'bus-bars and incoming machine voltmeters mounted on a swing panel at the end of the control board.

A tumbler switch is inserted in the D.-C. supply to the trip circuit, so that all protective devices may be rendered inoperative if desired.

The Merz-Price device is intended to act in case of failure of the cables from the switch cell to the generator or of the generator windings.

For this purpose each of the three-phase windings is taken through a current transformer in the bed-plate of the generator

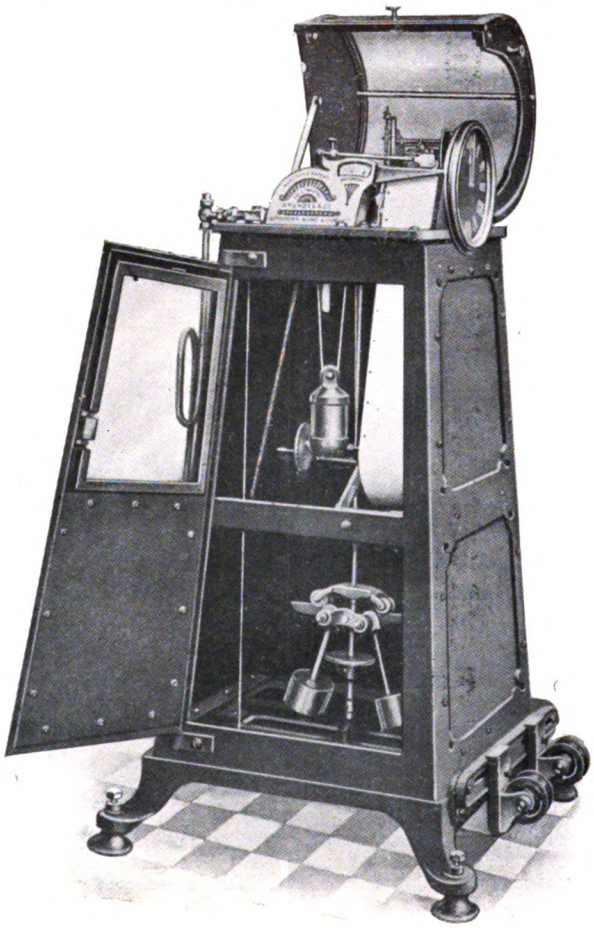

FIG. 2.—MOSCROP'S SPEED RECORDER.

before being connected together at the star point. Their secondaries are connected to the control board by L.-T. four-core armoured cables, and are there so connected to the L.T. cables from the current transformers in the oil circuit-breaker cells that the two sets of transformers are normally sending current in the same direction round the circuit connecting them and containing the indicating and measuring instruments. Fuses are inserted in this circuit which will blow with 75 per cent. excess current.

The instantaneous relays will only operate with a voltage considerably in excess of any voltage that can be reached by the current transformers in normal circumstances, even with three to four times full load current, and they are connected in parallel with the transformers. The operation of the gear is as follows:—

In normal circumstances, when the generator is delivering current to the bars, L.T. current circulates at a low voltage through the two current transformers, instruments, and fuse, practically nothing going through the relays. Should an overload take place the fuses blow, and the only path for the current from one set of transformers is through the relays, which immediately act, and close the circuit through the trip coils of the oil circuit-breakers, the other set of transformers being on open circuit.

Should the cables or windings fail, E.H.T. current will flow in opposite directions through the two sets of transformers, the secondary voltages of which are consequently in opposition, and a voltage rise will take place whose value is dependent on the open circuit voltages of the transformers, and the relays will operate. It is not necessary for an actual reversal to take place; a sufficiently large difference in the currents at the two ends would have the same effect.

The auxiliaries of the turbo-generators, which, it will be remembered, are electrically driven, are controlled on the E.H.T. side by a substation board of the concrete cellular type, which had been previously used at the Manchester Exhibition, and on the L.T. side by a flat back board. This "substation" is also a recent addition at Stuart Street. Hitherto, all the auxiliaries have been worked by continuous current supplied by motor-generators, but in future all the auxiliaries will be driven by three-phase motors. Three transformers, each of 250-kw. capacity, are employed.

In remodelling the switchgear in the station, it has been divided up into three sections, one of which is that just described, which is in connection with the two 6,000-kw. sets. The second section, also supplied by Ferranti's, controls the two 3,750-kw. Wallsend-A.E.G. sets, and the third section, supplied by the

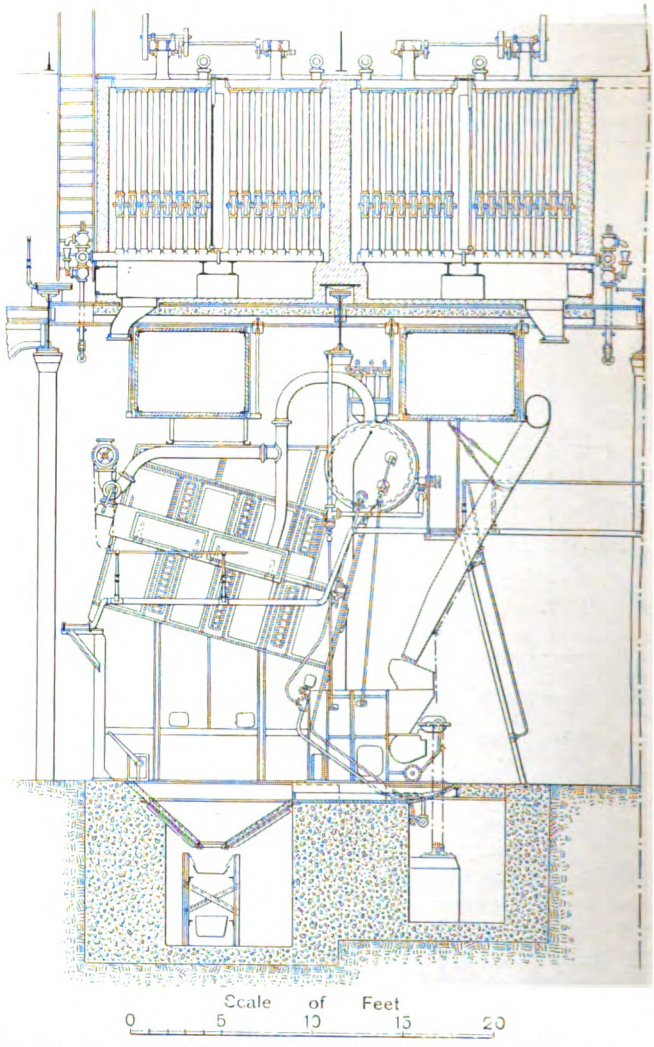

FIG. 3.—SIDE ELEVATION OF B. & W. MARINE-TYPE BOILER AT STUART STREET.

Westinghouse Co., controls the six 1,500-kw. Yates & Thom-A.E.G. sets. Each section has a distinct switchboard, and supplies its own set of feeders, but the sections are inter-connected by group switches, which are normally closed so that the whole station is run in parallel. Each section has also duplicate main 'busbars.

Another recent addition to the station is a Tudor battery in a separate battery-house adjoining the station, which is used for excitation and the D.C. auxiliaries. It has a capacity of 1,200 ampere-hours at the one-hour discharge rate.

Some interest attaches to a Moscrop speed recorder made by Messrs. Arundel and Co., of Stockport. In view of there being a certain number of textile mills connected to the mains, an absolutely constant frequency is necessary.

The general arrangement of the recorder is seen in Fig. 2. The instrument is belted to one of the synchronous motor-generators which supplies the station D.-C. auxiliaries and the excitation. A chart is moved along by clockwork in the ordinary way, and a simple governor gear actuates a pencil, which records the speed variations on the chart. Two relay contacts actuate a switch, which switches on lights (red or white) at intervals along the switchboard gallery to indicate if the speed is too high or too low.

To supply steam to the new generating sets, two large B. & W. boilers are already in operation, and two are in course of erection. These four boilers are of the "marine" type as manufactured for land purposes. It may be mentioned incidentally that all the boilers at Stuart Street, now 40 in number, are of Messrs. Babcock & Wilcox's make, although it is only the last four which are of the marine type. The saving of space in this pattern, owing to the diminished depth, is clearly seen in Fig. 3.

Each of the four new boilers has 6,725 sq. ft. of heating surface, and consists of 38 sections of tubes $3\frac{5}{8}$ in. diameter, each section having 16 tubes 11 ft. 9 in. long, the whole surmounted by one 54-in. drum. The tubes are expanded into steel headers back and front, and each boiler is fitted with an integral superheater having 1,156 sq. ft. of heating surface and capable of providing a superheat of 200° F. The working pressure of the boilers is 200 lbs. per sq. in.

Each boiler is fitted with two of the company's latest pattern of chain-grate stokers, each 7 ft. wide by 12 ft. long, driven through a link chain and sprocket wheels from a shaft arranged underground.

The normal evaporation of the boilers when working in conjunction with a Green economiser of 384 pipes, and with a draught not less than $\frac{5}{8}$ in., is 32,000 lb. per hour, but they can be forced to 40,000.

Some years ago Messrs. Babcock & Wilcox installed two gravity bucket conveyors at these works, which handle coal to the main bunkers, and are also arranged to take the delivery of ashes from the two tray conveyors which have been applied to the four new boilers above mentioned. Coal is fed to the stokers of the new boilers from the main bunkers by means of bifurcated chutes, with regulating valves operated from the firing-floor, the delivery into either stoker of each boiler being effected by means of deflecting plates in the chutes. For dealing with ashes, a tipping-tray conveyor is arranged under each row of boilers and immediately under the ash hoppers situated at the back of the chain-grate stokers. These hoppers are provided with special valves, which regulate or cut off the flow of ashes into the tray conveyor. The ash-tray conveyors are arranged to deliver the ashes into the portable filler of one of the main gravity-bucket conveyors, by which the ashes are carried to the ash bunker.

In concluding this article, we must express our thanks to Mr. S. L. Pearce, the City Electrical Engineer, and also to the various contractors, for assistance in its preparation.

ELECTRIC DRIVING OF PRINTING PRESSES

The Holmes-Clatworthy System

IN view of the interest which has been aroused in the application of electric driving to large rotary printing presses, by the recent lawsuit between Messrs. J. H. Holmes & Co. and the Associated Newspapers, Ltd., we give the following description of the system developed by Messrs. J. H. Holmes & Co., of Newcastle-on-Tyne under the Clatworthy patent. Many large newspaper offices both in the United Kingdom and abroad have been equipped on this system, the total B.H.P. of the sets installed aggregating over 6,000.

For rotary presses it is essential that the machines may be capable of being driven at a slow speed for leading in the web of paper, that small movements may be made for putting on the stereo plates, &c., and that a gradual acceleration until full speed is reached may be obtained without any jerk or shock. In the "Holmes-Clatworthy" system this is effected by employing two motors as illustrated in Fig. 1. The large motor is coupled direct to the main press shaft, and the auxiliary motor is geared to the shaft of the large motor through a worm and worm-wheel. A self-releasing clutch is interposed between the worm-wheel and the large motor, so that the latter can overrun the auxiliary motor. The press is *always* started up on the auxiliary motor, and, before this motor has reached its maximum speed, the large motor (which is then being rotated at a slow speed) is switched into circuit by the continued movement of the controller, and shares the load with the auxiliary motor. The press speed continues to accelerate until the auxiliary motor is overrun by the large motor. At this point the clutch releases itself, and this motion is utilised for the purpose of closing a circuit to a switch which cuts off the current from the auxiliary motor.

By combining the main and auxiliary motors in this way, a self-contained driving unit which is capable of being attached at one point to a printing press is obtained. Such ratio of gear as is employed between the main motor and the driving press of the shaft is taken advantage of by the auxiliary motor through the worm-gear, so that there is a very large multiplying leverage between the auxiliary motor and the press. It is said to be impossible with this system for the man in charge to make any mistake in switching on the motors, as the complete cycle of operations has to be gone through after every stop, and he can give his undivided attention to the printing press without having to think whether he is operating the right handle or not.

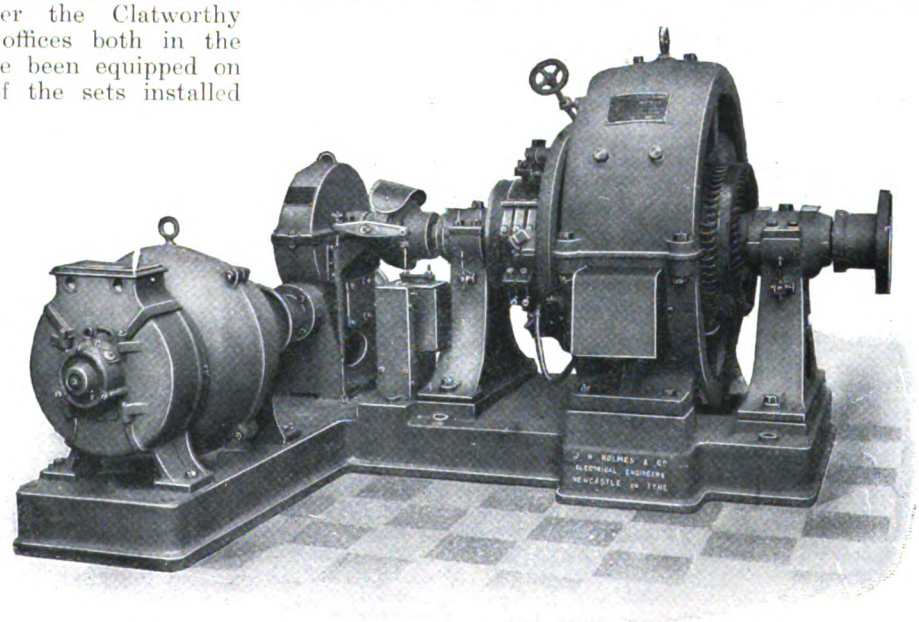

FIG. 1.—HOLMES-CLATWORTHY MOTOR EQUIPMENT FOR ROTARY PRINTING PRESS.

In the latest equipments, the whole control is effected from push-button switches placed on the press. There are three buttons at each control point, "up," "stop," and "down." These buttons are in the control circuits, which also include the solenoids on the main switch-board, illustrated in Fig. 2. The centre panel of this board holds the motor-operated rheostat in which the starting and controlling rheostats of the two motors are combined. The upper contacts are the series resistance starting steps of the small motor, the next series belongs to the large motor, and the last set on the other side of the spindle is the shunt speed control of the large motor. Between

Digitized by Google

the motor which drives the vertical spindle and the panel is the magnetic band brake. This latter is always on when the spindle motor is not running, but directly the "on" or "down" buttons are pressed, the brake is released and the motor started. On the bottom of the left-hand panel is the main circuit-breaker, and above this is the main solenoid operated switch.

An important feature of the system is the provision for hand operation in case of failure of the automatic control. If a push-button sticks, or if the spindle-motor is damaged, the small change-over switch on the right-hand panel is switched over. This cuts out the automatic control and releases the band brake on the rheostat spindle. The motors are then controlled by means of the double-pole switch on the right-hand panel and the handle on the rheostat spindle.

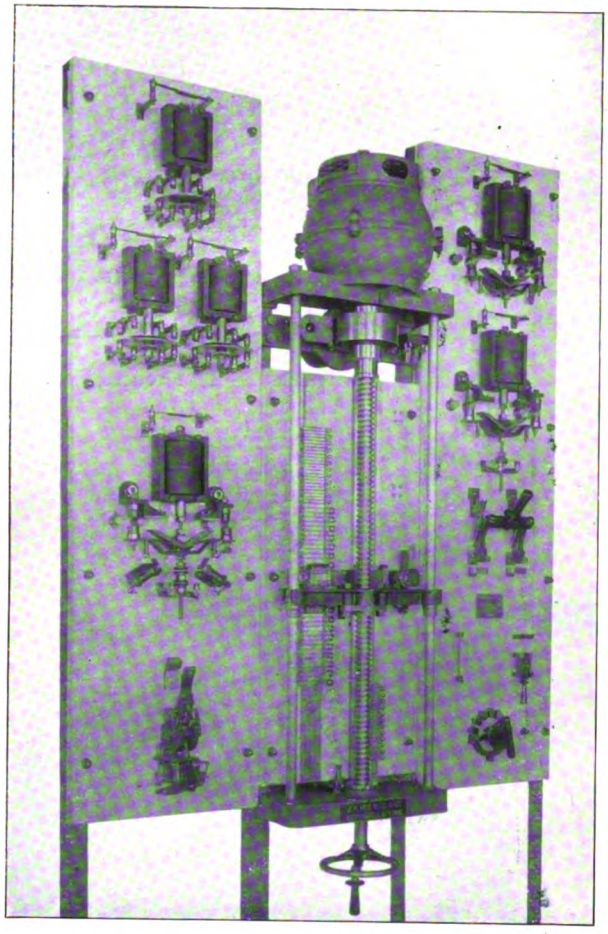

FIG. 2.—HOLMES-CLATWORTHY MOTOR-OPERATED RHEOSTAT FOR PUSH-BUTTON CONTROL.

BRAKE BLOCK COEFFICIENTS OF FRICTION

THE current Official Circular of the Tramways and Light Railways Association contains a report by Prof. Ernest Wilson on a number of experiments carried out by him at King's College, London. The experiments were made to determine the coefficients of friction of brake blocks of various materials under different circumstances, and the apparatus used consisted of a Brill undertruck with 30-in. chilled tyred wheels and 6-ft. wheel base, two Dick Kerr 35-b.h.p. series motors, controller, and rheostats. The materials were used as linings for four cast-iron shoes, and were oak and poplar, with the grain horizontal, Frood's waterproof lining, and soft grey cast-iron. The temperature of the tyre surface was taken, and peripheral velocities up to 1,940 ft. per min., and specific loadings up to 120 lbs. per sq. in., were dealt with. The only lubricant used was water.

The coefficients measured at a speed of 15 m.p.h., and with a specific load of 60 lbs. pr sq. in., and with clean water lubrication were as follows:—Oak, 0·032; poplar, 0·040; Frood's lining (black), 0·030; and plain grey cast-iron, 0·26. With a specific load of 100 lbs. per sq. in., the values were 0·043, 0·053, 0·045, for oak, poplar, and Frood's lining respectively. The temperature of the wheel surface varied between 35° and 50° C. The coefficients decreased with the speed; thus for oak at 60 lbs. specific load, the figures were:—7 m.p.h., 0·037; 15 m.p.h., 0·032; and 22 m.p.h., 0·028. Comparing these results with the tests published by the Tramways and Light Railways Association, and the Municipal Tramways Association, the author finds his own results lower in all cases with the exception of cast-iron. The figures obtained in the dry tests with a specific load of 40 lbs. and a speed of 15 m.p.h., were as follows:—Oak, 0·40; Frood's lining (black), 0·48; Frood's lining (green), 0·46; cast-iron, 0·3. In these tests the coefficient was found to fall with an increase of load at a given speed; the opposite effect was observed with water lubrication. As compared with the results obtained by the Tramways and Light Railways Association, the figures of the present tests are somewhat higher. Both tests show that cast-iron diminishes its coefficient with increase of speed for a given load.

Concluding, the author states that the figures obtained emphasise the possible effect of water upon friction coefficients with the non-metallic substances quoted, and if it were not for the fact that road material mixed with water increases the coefficient it would be difficult to believe that these substances could be trusted in wet weather for track brake purposes. Under dry conditions—for instance, in tube railways, and possibly for ordinary railways where the blocks can be kept dry—they should give very good results. Frood's lining is already doing very good service on underground railways. It produces a beautiful polish on the tyre surface and does not wear it away, and the coefficient is high. Poplar is a wood which produces similar results to Frood's lining when once it is bedded. Once or twice, with water lubrication combined with low temperature, the motors have raced with a specific load of 120 lbs. per sq. in. in the case of non-metallic linings, and the author has misgivings as to their general reliability for tramway purposes. It is just when a car is about to descend an incline that the worst possible conditions may obtain. The blocks may be saturated with water and the temperature of the wheels and blocks may be low. The coefficient will not be sufficient in the first few seconds to generate the heat required to evaporate the film of water between the blocks and wheels, with the result that racing may occur.

ACCIDENTS WITH CHARGED TROLLEY STANDARDS

THE following letter calling attention to the necessity for precautions for preventing the possibility of trolley standards becoming "alive" is being circulated among tramway authorities by the Board of Trade:—

I am directed by the Board of Trade to draw the attention of your Council (or Company) to a fatal accident which occurred on May 21st last, on the Wolverhampton District Electric Tramways to a passenger named Benjamin Cole. The man was found dead on the top deck of a car with his feet (on which were nailed boots) resting on the base of the trolley standard and the upper part of his body against the handrail. In accordance with the medical and other evidence, the Coroner's jury found that death was due to electric shock. The Board of Trade appointed their Electrical Adviser (Mr. A. P. Trotter) to hold an inquiry into the matter. In the course of his inspection of the car signs of a considerable arc were found on the brass bolt by which the main cable is attached to the trolley head; arcing had taken place between this bolt and the trolley boom at a distance of only about half an inch from the extreme end of the boom, at a place where it was not likely that there had been any mechanical abrasion of the insulation. Mr. Trotter was of opinion that the defect was probably due to a chip of metal in the taping with which the brass bolt was insulated. In addition to this defect, there was a failure of the red lamp warning, due to a discontinuity in the wiring of the lamps. On the car being stripped, the wire was found to be open-circuited behind one of the corner pillars. Your Council (or company) are doubtless aware that owing to the drawbacks attaching to the red lamp warning, the Board of Trade have expressed their preference for an audible signal; and as a result of the accident the Birmingham and Midland Tramways Joint Committee who work the line have decided to make a daily test to see that the trolley standards are properly insulated, and to equip all cars with a magnetic blow-out fuse giving a distinctly audible signal. The Board are advised that, pending the adoption of an audible signal, the lamps should be bridged with a suitable fuse, and that the signal device should be tested at least once a week; and they would be glad if your Council (or company) would give this matter their careful consideration, and in due course inform the Board of any steps taken to prevent danger to passengers arising from the cause in question.

British Association of Medical and Electromedical Instrument Manufacturers.—An Association, which includes among its members a number of well-known electrical firms, has been formed with the above title, with the object of securing conjoint action in the interest of the trade, and to conserve the interests of the firms represented at the various exhibitions, &c. The President is Mr. H. E. Donnithorne, and full particulars can be obtained of the Hon. Secretary, Mr. Geoffrey Pearce, of "Nairn," Avondale Avenue, Woodside Park, N.

ELECTRIC CARS AND ELECTRICAL ACCESSORIES AT THE OLYMPIA EXHIBITION

OWING to the discontinuance of the annual winter display of automobiles in Paris, the exhibition promoted by the Society of Motor Manufacturers and Traders now being held at Olympia is of even greater importance than usual. The show is, of course, principally devoted to petrol cars of every type suited for private use, and many sumptuous examples of the carriage builder's art are to be seen. From this point of view, it has a completeness and air of prosperity showing, except perhaps for the slightly reduced number of exhibitors in the complete car section, few signs of the depression due to over-production from which the pleasure car trade has recently been suffering. It is our purpose, however, to direct attention more particularly to a few of the features of electrical interest which are present.

The purely electric or battery-driven car is not well represented, and this may be partly due to the fact that in London more attention is being paid at present to the hiring out of these vehicles from central garages than to their sale to private owners. Several well-known makes are absent, and, indeed, there is only one stand, that of the ELECTRIC VEHICLE Co. (14 to 16 Cockspur Street, Stand No. 101) devoted entirely to cars of this kind.

This firm have a novelty in the shape of a small two-seated electric car with hood, in external appearance, like a petrol voiturette. This is driven by a shunt-wound single commutator motor under the floor by a cardan shaft and live axle, and carries a 105-ampere-hour, 44-cell Tudor battery, partly in the bonnet, and partly under the seat. The whole vehicle weighs only 11½ cwt., of which the battery is responsible for about 6 cwt., and is said to be capable of 40 to 50 miles on one charge, and a maximum speed of 18 miles per hour. The controller has four positions, and is worked by a conveniently placed side lever; one of the pedals also works a circuit-breaker. It should be mentioned that the price of the complete car is only £250, and we are informed that the Tudor battery Co. are prepared to arrange for maintenance contracts for the batteries. Another car of similar nature, with a somewhat different body, and a single driver's seat, and no bonnet, is also shown, and the centre of the stand is occupied by an open electric touring car with a much larger battery, which is stated to have travelled from London to Brighton and back, and then to have run a further 20 miles in London without recharging.

Another interesting electric car is the "Cedes Electric" brougham, exhibited on Stand No. 1 by the Austrian Daimler Motor Co. (15 and 16 Cockspur Street). The drive on this car is gearless, and the motors are contained in the hubs of the back wheels.

Reference to this car as shown at a former exhibition appeared in ELECTRICAL ENGINEERING, Vol. II. (November 21st, 1907), page 797. A notable feature of the Mercédès hub motor is the flat radial commutator, and another point of interest is the provision on the controller for electric braking, which gives a certain amount of recuperative effect on the battery.

An electric car of the latest standard Opperman pattern, in which the drive is entirely through enclosed chains, was to have been shown on the stand of the BRITISH ELECTROMOBILE Co. (5-6 Halkin Street, S.W.), but was, unfortunately, crowded out.

No examples are presented of petrol-electric drive as applied to touring cars, and it seems to be principally for heavy traffic that developments in this direction are taking place, although there are rumours of the early appearance of more than one moderate-powered chassis equipped on this system.

The exhibitors of electrical apparatus, including ignition appliances, lamps, batteries, &c., in the crowded accessories section in the gallery, are very numerous, and no attempt will be made to give a complete list. It may be of interest, however, to mention a few examples either as novelties or as indicating prevailing practice.

Electric ignition in by far the largest number of modern cars is carried out by means of magnetos, usually of the high-tension variety, but most of the makers of ignition appliances provide for the alternative of batteries, in a so-called dual ignition system, not so much on account of unreliability of magnetos as to provide for easier starting and to "make assurance doubly sure." Sometimes the battery arrangement is reduced to a mimimum intended only to ensure starting "on the switch," but in the more elaborate equipments the battery ignition may be relied on for long periods.

A good example of both these arrangements is seen on Stand No. 270 of NILMELIOR (ENGLAND), LTD. (36-37 Albert Place, Tottenham Court Road), which firm represents the interests formerly known by the names Bassée & Michel. In the self-starting arrangement, a standard high-tension magneto is employed, but the connection between the H.T. end of the armature and the distributer is interrupted by a switch. This is contained in the same case as the particularly small starting coil on the dashboard, and is closed automatically by a spring as soon as the engine has been started by the push-button connected to the coil. As this coil is only used for starting, dry batteries are sufficient, and accumulators need not be carried, unless required for lighting. The full dual ignition is similar, but with a larger coil supplied by storage batteries, and with the change-over switch worked by hand. The new form of Bosch dual ignition system shown by the BOSCH MAGNETO Co. (23 Store Street, W.C., Stand No. 192) also employs a neatly arranged vertical dashboard coil, combined with change-over switch and starting push-button, and, as in most modern systems, simplicity in wiring is attained by the use of the same distributer and plugs in both cases. A special form of plug is used, insulated with prepared steatite. The new "Hall-E.I.C. System" of the ELECTRIC IGNITION Co. (Sampson Road North, Birmingham, Stand No. 275), has a foot switch, which, when pressed, works the starting contact, and when shifted sideways actuates the change-over switch. The magneto employed is distinguished by its large ball bearings and the fact that it is driven by a worm gearing at a lower speed than the distributer on the worm-shaft. A notable feature of the coil is the use of a laminated core with double closed magnetic circuit for the coil in place of the usual bundle of soft iron wires. Messrs. J. C. FULLER & SON (Woodland Works, Old Ford Road, Bow, E.C.) also exhibit a dual H.T. system on Stand 253, in which a coil within the field magnets of the magneto is used both with magneto and with the battery, so that the only apparatus on the dashboard is a combined starting and change-over switch. Messrs. C. A. VANDERVELL & Co. (Warple Way, Acton Vale, W., Stand No. 243), however, are among those who employ an entirely separate coil for use with the battery. In the Nieuport dual system, shown by Messrs. VAN RADEN & Co. (Great Heath, Coventry) on Stand 173, the distributer is driven separately from the magneto, and a very neatly arranged combined trembler coil, starting button, and change-over switch is used. The working parts are ingeniously reduced to a minimum by making the coil itself carry both high- and low-tension contacts and rotate with the switch lever. A dual ignition system is also shown by Messrs. THOMSON-BENNETT, LTD. (Arden Works, Heneage Street, Birmingham) on Stand No. 271, in which the magneto, distributer coil, and change-over switch are all separate. The high- and low-tension magneto of the SIMMS MANUFACTURING Co. (Kimberley Road, Kilburn, N.W.), shown on Stand No. 257, are too well known to need description. Forms suitable for gas-engines as well as motor-cars are shown. In this firm's self-starter the high- and low-tension windings of the magneto armature itself are used instead of an auxiliary coil, and a neat press-button arrangement is provided on the dashboard. Another well known magneto is the Eisemann machine, shown among various other electrical accessories on Stand No. 167 by UNITED MOTOR INDUSTRIES, LTD. (46 Poland Street, W.).

Coils for ordinary battery ignition, both for the system with separate coils for each cylinder, and for use with high-tension distributers, are shown by a number of firms.

The now well-known system devised by Sir Oliver Lodge, in which the actual ignition spark is a secondary spark caused by the sudden overflow of a pair of condensers, is to be seen in operation on Stand No. 234 of Messrs. LODGE BROS. & Co. (14 New Street, Birmingham). The patterns of coil shown include a new, very compact multi-cylinder coil, with one trembler, a single cylinder coil, as well as the earlier pattern, complete with alternative tremblers and change-over and reversing switches mounted inside the case. Another novelty is the Lodge double-pole plug, with both terminals insulated, which renders it possible to have two or more sparking points in series in the same cylinder, an arrangement claimed to give increased power. A very large variety of other ignition appliances, including contact-makers, distributing plugs, batteries, switches, wires, special terminals, &c., are shown in the gallery, most of which call for no special remark.

The use of electric lighting on motor-cars is considerably on the increase, and a great number of special fittings and appliances are shown. Accumulators of somewhat larger size than

Digitized by Google

usually made for ignition purposes are usually employed, and a few firms are providing a solution to the charging problem by means of small dynamos arranged in a similar way to train lighting machines and driven off the engine.

An example of this is the equipment shown by the ELECTRIC IGNITION Co., which is really a miniature train-lighting machine on the well-known Lahmeyer principle. Messrs. C. A. VANDERVELL & Co. also exhibit an apparatus on the same lines. In these sets the dynamo gives a practically constant voltage over a considerable range of speed, and an automatic cut-out disconnects from the battery when the engine speed falls below the lower limit. The output of the machine can be adjusted to suit the requirements of the battery by a special field regulator. Messrs. PEIO & RADFORD (100 Hatton Garden, E.C., Stand No. 174) have also introduced a new and very small machine for this purpose. This is provided with an automatic centrifugal coupling, which slips when the speed exceeds a certain value, and also a solenoid cut-out which acts when the voltage drops. This apparatus gives an output of 50 watts, and does not exceed 22 lbs. in weight.

Among the many forms of electric side and head lamp shown, special mention may be made of the "Sylverlyte" lamp to be seen on Stand No. 224 of the MOTOR SUPPLY Co. (110-111 Piccadilly, W.). This lamp throws a powerful, well-directed beam free from dazzling glare, and is provided with a combined reflector and lens, consists simply of a solid conical block of the finest Jena glass with a convex lens surface. A 14-c.p. lamp is inserted in a central cavity in the glass. Notwithstanding its name, no silvering is used, as the reflection is entirely from the special shaped conical interior surface of the glass. The rays are further concentrated by the convex front surface. Metal filament lamps are practically universal for this class of work, and a two-filament lamp is shown on Stand No. 167 of the ROTAX MOTOR ACCESSORIES Co. (45 Great Eastern Street, E.C.), in which a twelve-volt filament is employed for head-lights in the country, but when in town a four-volt filament is used.

Electric horns are present in profusion. One of the most powerful, if not the most pleasing in sound, is the Mira electric horn shown on Stand No. 179 by the HIGH TENSION Co. (1A Guildford Street, W.C.). In this apparatus a vertical-shaft miniature motor, complete with eight-part commutator and slot-wound armature, and provided with ball thrust bearing, causes two loose strikers to fly out by centrifugal force and tap on a steel diaphragm. The little motor, when wound for four volts, takes two amperes. Other electrical accessories include signalling devices for transmitting orders to the driver, and a few of the "speedometers" are actuated electrically, including the "Warner" instruments of the ELECTRIC AND ORDNANCE ACCESSORIES Co. (Cheston Road, Birmingham), in which the rotation of a permanent magnet exerts a torque upon a spring-controlled aluminium disc. Mention may also be made of an electrically-heated vulcaniser for tyre repairs, shown by Messrs. PEIO & RADFORD. This is arranged for connection to an ordinary supply circuit, and contains a thermostat which cuts off the current directly a certain temperature is reached. Special precautions are taken to prevent sparking at the contacts.

Before concluding, attention may be drawn to a novelty included in the display of machine tools in the gallery made by Messrs. DRUMMOND BROTHERS (Church Hill Works, near Guildford) in the shape of a new design of light universal grinding machine. This is arranged for cutter grinding, flat grinding, parallel and taper outside and internal grinding. Mounted on the travelling slide is a swivelling table carrying a headstock with hollow mandrel coned and split at both ends, with two interior coned sleeves mounted on a short screwed portion of the mandrel, giving a quick and accurate hold for chuck mountings, &c., or for gripping work passing through the mandrel, by the use of split sleeves. The intermediate drives are concealed in the body of the machine itself, and there is no countershaft whatever. A recent design of radial drill and several small lathes are also shown.

The whole exhibition showed a completeness on the opening such as is rarely attained, and the one criticism we have to make regarding its arrangement is that, in their enthusiasm in providing ample space for the exhibits, the management have not sufficiently studied the convenience of those desiring to see them, with the result that the gangways are narrow to a degree that often makes them impassable.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

LAMPHOLDERS, SWITCHES, AND ACCESSORIES.—A new edition of the accessories catalogue of the Edison & Swan United Electric Light Co. (Queen Street, E.C.) has been issued. The present edition has been entirely revised, and whilst a number of the goods listed have been improved in details, and many prices have been reduced, there are also several important additions. Amongst these may be mentioned a new type of counterweight with specially heavy brass parts, together with several different types of combined wall sockets and plugs. The well-known Phlatta switch is also listed in several ornamental designs, and there are a number of strikingly handsome patterns of fancy switch-plates included. Worthy of particular notice is a new push pattern pear-switch, with key-holder movement, together with other designs fitted with tumbler action. The construction of these appears to be strong and reliable, and the switch is easily operated with one hand. The heavier types of quick make and break knife-switches, double-pole house service or motor switches, and special ironclad switches are also included, together with battery regulators, &c. There are many new and improved forms of cut-out, of which one is an improved type, which is specially designed to comply with the most stringent regulations. A complete range of standard fuses of this type is now made; the terminals are mounted on English vitreous porcelain bases, which are designed so as to shroud the live fuse and live metal parts thoroughly, practically preventing all risk of arcing. The porcelain bases are mounted in a cast-iron case, asbestos lined, and fitted with insulated bushes. A number of designs of Edi-swan switchboards are included, and there are also several pages dealing with small accessories, such as jointing materials, insulators and ironwork, wiring cleats, casings, cable sockets and connectors, and fusible wires. Altogether the list is very complete, and has evidently been most carefully compiled, and should prove of considerable use to a wide circle.

TANTALUM LAMPS.—The latest addition to the series of foreign show-cards relating to these lamps is reproduced in the

ITALIAN TANTALUM LAMP SHOW-CARD.

accompanying illustration which has been sent us by Messrs. Siemens Brothers Dynamo Works, Ltd. (Tyssen Street, Dalston, N.E.).

ELECTRIC CLOCKS.—An illustrated catalogue is to hand from the Reason Manufacturing Co., Ltd. (Lewes Road, Brighton), giving particulars of a new electric clock system. The master clock is an electrically-controlled pendulum mechanism with a special noiseless form of contact device for transmitting the periodical impulses to the secondary dials, which are also noiseless. The improvements embodied in these clocks are protected by the Murday patents, the manufacturing rights of which have been taken up by the Reason Co. Self-contained electric clocks with the same movement are also listed.

TRACTION METER.—A new pamphlet from Messrs. Ferranti, Ltd. (Holinwood, Lancashire) describes a pattern of mercury ampere-hour meter specially designed for use on tramcars to obtain economy by providing a check over the current consumed by every individual car and driver. The Ferranti traction meter is a modification of the standard house service type, but is the same in general appearance and construction To meet the heavy vibration, the following improvements have been made, so that supporting springs are not required :—The bottom jewel is supported by a spring; the meter is heavily shunted and has a very light rotor; the pivots are much stronger and the bottom one is not so pointed, having a blunted round end; there is no top jewel, simply an ordinary bearing; and the terminals are embedded in a new insulation.

METAL FILAMENT LAMPS.—A series of comical cards which defy description have been issued by the British Thomson-Houston Co., of Rugby, in connection with their well-known tungsten lamps. These designs, which are the work of a caricaturist of no mean ability, have, like the lamps themselves, their origin in the works at Rugby.

RECENT PROGRESS IN HEAVY ELECTRICAL ENGINEERING

THE opening meeting of this session of the Institution of Electrical Engineers on Thursday last commenced with the presentation of a memorial bust of the late Dr. John Hopkinson, referred to on another page of this issue. The retiring president, Mr. W. M. Mordey, then called upon Dr. G. Kapp to take his place and read his inaugural address. Previous to the reading of the address, Mr. Alexander Siemens proposed that the thanks of the Institution be accorded to Mr. Mordey for his work during the past session, especially that in connection with the acquisition of the new building. Mr. J. Swinburne seconded the motion, which was briefly replied to by Mr. Mordey. Dr. Kapp then read an abstract of his address. A photograph and biography of Dr. Kapp appeared in our issue of April 22nd, 1909, p. 363.

After referring to the growth of the Institution, Dr. Kapp gave figures which showed that the total capital invested in the industry had increased from approximately 106 million in 1899 to nearly 386 million in the present year. The number of skilled men employed (as indicated by the I.E.E. membership) had only nearly doubled in the same time, so that the efficiency of labour might be said to have increased by about 70 per cent.

Speaking of generating plant, Dr. Kapp pointed out that the modern tendency is to instal very large units, and he gave examples of single units up to 14,000 kw. In most modern electricity works the circulating and air pumps were driven by electric motors, but this method had been replaced at the works of the Allgemeine Elektricitäts Gesellschaft by an arrangement of turbo-driven centrifugal pumps, even including a form of centrifugal air pump, which he described. Considerable space is saved by the system, and it is stated that the feed water obtained is absolutely free from air, and no oil filters are required. An important development was the use of exhaust steam turbines. He mentioned an example of an installation of this class at a German mine, where an annual saving of £20,000, or 34·5 per cent. of the capital outlay, was obtained.

Passing on to questions of dynamo design, Dr. Kapp described a method of obtaining a large drop with low inductance and demagnetising force of the armature, devised by Mr. Miles Walker and adopted by the British Westinghouse Co. for turbo-alternators. The exciting coils in the rotor are arranged with the centre of the coils near to the leading edge of the pole, so that the teeth in that part of the rotor are more strongly magnetised than the teeth in the polar axis, whilst the magnetisation is weaker still in the teeth in the lagging polar edge. Normally, the armature currents weaken the induction over the leading and strengthen it over the lagging polar edges, and, on the whole, there may be no change or even a slight rise of total flux with an increasing load, so that the armature back magnetisation is compensated. This compensation fails, however, if owing to a short there is a great increase in armature current, for then this current lags so much that the pole as a whole is demagnetised, and the machine is in no worse condition than a machine of the usual type designed for a small short-circuit current. Referring to the use of non-synchronous machines as generators, Dr. Kapp mentioned that a 5,000-kw. non-synchronous generator had been added to the plant of the Inter-borough Rapid Transit Company, New York. Prof. Niethammer advocated the use of such generators in connection with converters for railway sub-stations, in which case no other source of alternating current would be required, the converter itself producing the excitation of the generator. To meet the difficulties in the design of turbo-alternators for very low periodicities, Mr. E. Ziehl had devised a type of alternator comprising a non-synchronous machine having the same three-phase winding in stator and rotor, and the circuits connected either in series or parallel so that a three-phase current sent through the machine produces fields which in stator and rotor revolve in opposite sense. If the rotor be driven in a sense opposite to that of its own field and at a speed corresponding to twice the frequency, the field produced by the rotor currents would in magnitude and direction of motion be identical with that produced by the stator currents. Thus each of the two windings contributes one-half of the field common to both. At the same time the demagnetising action of each winding is eliminated by that of the other. The machine must be excited from some synchronous generator; it cannot give a wattless current, and in an installation where the power factor is less than unity the synchronous machine must supply the wattless currents. When used in connection with converter sub-stations, no separate alternating excitation is required, the converter itself acting as exciter.

In transformers, he continued, there is also to be noticed a general tendency towards large units, even up to 10,000 kw. The reduction in weight of transformers is very remarkable. For example, in a certain Brown-Boveri 4,600-kw. transformer, the active material weighs only 3·124 kg. per kilowatt, and in an Oerlikon 3,500-kw. transformer the active iron only weighs 2 kg. per kilowatt output. This latter transformer is a dry transformer with forced draught, yet the voltage on the high-pressure terminals is 27,000 volts. Such an arrangement is safe enough in the pure air of the high Alps, but it would be risky to adopt it in a town like London for any but a moderate pressure. Generally, the modern tendency is to rely on oil for insulation, and, for units above a certain size, on water as the cooling medium. The Siemens Schuckert Werke have employed water, which is sprayed against the case.

Dr. Kapp then described briefly the Hunt cascade motor, and the new multiple-speed three-phase induction motor of Messrs. Brown-Boveri, as used in the latest Simplon Tunnel locomotives. Another important development was the application of the Deri motor to hoisting machinery, and also for driving ring-spinning frames, with automatic speed regulation. The original Winter-Eichberg motor had a series characteristic, but the winding can be altered so as to give the motor a shunt characteristic. The motor is started as a series machine, and when up to speed, or nearly so, it is switched over by its controller to the shunt condition. With a motor of this type the power factor is very nearly unity at all loads.

There has been a considerable development, continued Dr. Kapp, in the transmission of power in late years. In England a pressure of 20,000 volts may be considered as an upper limit for most cases, but on the Continent and in America higher voltages are very often adopted, reaching in Canada up to 110,000 volts. The voltage is limited not so much by the dielectric strength of the insulators as by dispersions of electricity through the air and the consequent loss of power. The connection of an underground cable with an overhead line constitutes a special danger. To protect the cable in such a case, Mr. Semenza, of Milan, has provided a kind of gigantic Faraday cage surrounding the point where the overhead lines from Paderno are connected to the Milan cables by transformers. The transformers, switches, lightning protectors, and accessory electrical appliances are placed in a large building. The iron parts of the structure are earthed, the roof and the window-frames are of iron, and under the plastering of the walls there is iron netting. A direct metallic connection between the overhead line and the cage would, of course, give absolute protection, but it was necessary to give the protection of a direct connection without actually making it. This problem Mr. Semenza has solved by making use of resonant circuits. Another recent invention has for its object the prevention of such an accident as that which happened last August in Olgiate, where several persons were killed by contact with nominally low-pressure circuits. This is a means to cut off the current automatically in the low-pressure circuit as soon as its potential to earth exceeds a predetermined limit, invented by Mr. Arcioni, of Milan. The essential parts are three electromagnets with shaded poles connected star fashion, with the centre point earthed, to the three wires of the low-pressure system. In front of the poles are the three legs of a star disc mounted on a counter-weighted spindle. As long as the three wires have normal potential difference to earth the torque exerted by the shaded poles is insufficient to raise the weight, but if through infiltration of high pressure the electrical centre is displaced the torque increases, the weight is raised and makes contact in a relay circuit, which then trips the main switch. If the weight is adjusted to rise at double normal torque, the apparatus also acts if one of the low-pressure wires should go to earth. Dr. Kapp then referred to the mistaken idea that cheap electrical power could only be obtained where there was abundant water power, and described briefly the development of "waste heat stations" in the North-east Coast power system.

Turning to electric railways, Dr. Kapp said that he was compelled to restrict his remarks to A.-C. systems. I am quite aware, he continued, that there are some enthusiastic adherents to the direct-current system who recommend working main lines by overhead wire at some 3,000 volts, but the majority of practical men hold that alternating current in some form or other must be the means to supply power to the traction motor. The only question on which there may be still difference of opinion is whether the current shall be three-phase or single-phase.

Digitized by Google

Electricians prefer the former, railway men the latter. As the railway men are in reality the customers who give the order to the electrical engineer, it seems likely that the single-phase system will be the one more generally adopted. The Italian Government have decided to electrify eleven sections on the State railways, aggregating 337 miles of track, on the three-phase system. In the case of three lines, the service is extremely heavy, trains of 400 tons and over having to be hauled up on long grades of 2·5 to 3·5 per cent. at a speed of 45 km. per hour. With the three-phase system it is possible to comply with these conditions by using two 2,000-h.p. locomotives weighing each 60 tons. With the single-phase system the weight of the motors would be at least doubled, and, in the circumstances, the advantages of wider speed adjustment in running and better efficiency in starting were not of importance. It is, however, probable that some other lines will be worked single-phase.

Referring to the work of the committee appointed by the Swiss Government, Dr. Kapp said that the committee had not yet pronounced an opinion on the most suitable system, but he inclined to the belief that the decision would be in favour of the single-phase system, especially since by the use of the Deri type of motor it had been found possible greatly to simplify and also lighten the accessory equipment. The first test of this motor for traction was made on the three-phase Engelberg railway, one phase only being used. No resistances, auto-transformer, contactors, regulating switches, or controllers of the usual construction are required. The starting and the regulation is effected simply by shifting the brushes. With regard to frequency, the Swiss Committee recommends 15 periods as a standard, with a latitude of 10 per cent. up and down.

Dr. Kapp then touched on the subject of the electric driving of rolling mills, describing briefly the equipment of the steel works of Sir Alfred Hickman, Ltd., of Bilston, and the reversible mill of Messrs. Dorman, Long & Co., Ltd. The total horse-power used in Germany in electrified rolling mills and other heavy machinery in iron and steel works might, he thought, be estimated at considerably over 50,000 h.p.

Turning to electric steel furnaces, Dr. Kapp said that the electrical reduction of iron ore has not yet advanced much beyond the experimental state. A plant has been erected in Domnarfvet, Sweden, but the production is only about six tons a day. The consumption of coke is about one-third of a ton to the ton of pig produced, as against one ton in the case of an ordinary blast furnace. Against this saving must be set the cost of energy. This process could only be successful in a country where electrical energy is exceedingly cheap and fuel very dear. In the manufacture of steel from pig or the refining of steel the outlook is far more hopeful. Even where owing to the price of power the electric process is no cheaper than the thermic process, the former enables the steel refiner to achieve results with certainty and regularity which under the old methods are hardly attainable at all.

A description of the various types of electric furnaces was followed by a reference to the present rapid development of the application of electrical energy for the fixation of atmospheric nitrogen, special attention being drawn to the system of the Badische Anilin und Sodafabrik. Another interesting development was the direct application of electricity for the promotion of the growth of plants. On several experimental farms Sir Oliver Lodge and others had shown that there is an increase in the yield per acre of about 30 per cent., with a consumption of only 20 units per annum per acre. The system is in use on several farms in this country, on six farms in Germany, and on one farm in Holland.

Concluding, Dr. Kapp refers to the alleged backwardness of British manufacturers. He did not agree that British engineering works could not produce equally good plant as their rivals. There was no justification in reproaching British makers of electrical plant with backwardness. If, however, the reproach was levelled against the potential users of such plant, there was some justification. The great staple industries of this country were old-established and had been fairly prosperous for generations; those on the Continent were of recent growth, and had to struggle into existence against English competition. To become successful they had to adopt every improvement which science put at their disposal. With them the application of electricity was almost a vital matter; with us only a desirable improvement.

London Underground Railways.—The statement of receipts of the Underground Electric Railways Co., of London, for October shows that upon the District Railway there was a net increase of £2,900; on the Great Northern, Piccadilly, and Brompton Railway, £2,397; on the Baker Street and Waterloo Railway, £230; and upon the Charing Cross, Euston, and Hampstead Railway, an increase of £1,228. The London United Tramways Co.'s receipts, however, show a decrease of £5,660 for the month.

THE BIRMINGHAM LOCAL SECTION DINNER

MR. R. K. MORCOM, Chairman of the Birmingham Section of the Institution of Electrical Engineers, presided at the Third Annual Dinner of the Section last Friday. In proposing the toast of the Institution, he made an interesting speech, referring first to the subject of competition with the foreigner in the electrical industry. We need fear, he said, to meet no country in competition of brains. The present trouble of the British electrical industry, he insisted, is not due to insufficient training of our engineers or workmen, but to insufficient financial backing—perhaps cheap technical schools for financiers, he added, amid laughter, might be beneficial. Much interest was aroused by the following quotation which Mr. Belliss read from the introduction to "Stuart's Anecdotes of the Steam Engine," a book dating back to 1829. After estimating that in Great Britain 10,000 steam engines are daily doing more work than 200,000 horses or 1,200,000 men, and deploring the fact that these engines were yet only a name to the great bulk of the community, *even those engaged in manufacturing*, the following passage occurs: "This extraordinary indifference appears to have arisen from the operation of the remains of some ancient prejudices, biassing public feeling with regard to the class of mind necessary for the production of mechanical inventions. Even that philosopher whose discoveries have been described as links connecting the mind of Man with the spirit of God, is called by Dean Swift, 'That fellow Newton over the way, a glass grinder, and a maker of spectacles.'" This same superciliousness towards their profession, Mr. Morcom continued, was apt to extend at the present day to engineers themselves, although the avoidance of "shop" in their intercourse with one another was not so marked as with Army men. Mr. Morcom finished his speech by quoting the last six lines of "A Lady on Electric Light," verses which appeared in *Punch* in 1882, and had, he pointed out, even greater application now in view of the coming of the mercury vapour lamp:

"A veil may serve to screen from sun, but when in evening dress,
There's nothing 'twixt these awful lamps and female loveliness.
Then men of science you must aid and tell us, if you please,
How we shall make our charms withstand such glaring lights as these.
For if the ladies find the lamps still turn them pale and wan,
They'll lead a genuine campaign 'gainst Edison and Swan."

Dr. Gisbert Kapp, President of the Institution, in the course of his reply, said that the comparisons frequently made between this country and Germany were not just. It was not in making machinery and apparatus that we were behindhand, but in the use of it. Mr. Morcom was right to some extent in alleging a want of scientific appreciation on behalf of the financiers, but the real reason was that the German industries are younger than ours. The engineering industry in Germany resembled a baby that had to be fed on strengthening food, and that food was science. The Germans had recognised that without that they could not hold their own; with them it was a necessity, with us only a desirability. That the Continent is better supplied with water-power, he continued, is not sufficient reason for its relative greater progress, for it was a fallacy to imagine that, although they might have the water for nothing, the water-power cost nothing. In Italy itself, where there were both water-power and steam-driven stations, the former cost £40 per h.p., and the latter only £15 per h.p. In our coke ovens we had a useful cheap form of power comparable with water-power. Mr. Merz had estimated that in the north-eastern district alone some ¼ million h.p. were running to waste in the coke-oven gases.

Mr. Mordey, who proposed the toast of the Birmingham Local Section, gave some information as to the new Institution building mentioned elsewhere in this issue. In the remainder of his speech he insisted that the British electrical industry was not doing badly, and that the Institution of Electrical Engineers must not become a trade protection society. Mr. J. C. Vaudrey responded.

In replying for "the City of Birmingham," proposed by Mr. W. H. Patchell, Mr. R. A. Chattock referred to the large advance in the amount of power supply at high voltage (7,400 h.p. out of a total of 17,000 h.p.) from the Corporation mains.

Mr. J. F. C. Snell, who gave the toast of "The Electrical Industry," regretted the reluctance of the younger engineers to going abroad, although they should not forget that we owe our greatness to our aptitude for colonisation. Mr. M. Railing made a spirited speech in acknowledging this toast, replying effectively to Mr. Mordey, and putting clearly forward the manufacturer's point of view on the present situation. Finally, Dr. W. E. Sumpner drank to the health of the guests, for whom Mr. J. H. Rider responded.

Royal Society Medals.—Among the medals granted by the Royal Society this year are the following:—The Hughes Medal to Dr. R. T. Glazebrook, F.R.S., for his researches on Electrical Standards; the Davy Medal to Sir James Dewar, F.R.S., for his researches on Low Temperatures.

ELECTRIC TRACTION ON MAIN-LINE RAILWAYS

At a meeting of the Institution of Civil Engineers on Tuesday, November 9th, the following Papers were read: "The Single-Phase Electrification of the Heysham, Morecambe and Lancaster Branch of the Midland Railway," by Messrs. J. Dalziel and J. Sayers; "The Equipment and Working Results of the Mersey Railway under Steam and under Electric Traction," by Mr. J. Shaw; and "The Effect of Electrical Operation on the Permanent-Way Maintenance of Railways, as illustrated on the Tynemouth Branches of the North-Eastern Railway," by Dr. C. A. Harrison. The following are abstracts of these Papers:—

Single-Phase Traction on the Midland Railway.

The authors of the first Paper state that the electrification of the Heysham-Morecambe-Lancaster section of the Midland Railway was carried out on the single-phase system, as being more probably applicable to their future requirements than the direct-current system. This particular section line was chosen for experimental electrification partly because it could be worked from an existing power-station at Heysham. Though the traffic is light, it is long-hour throughout the year, so that there was scope for saving in working-expenses; also the summer traffic is heavy and liable to congestion. A description is then given more or less in detail of the principal parts of the overhead equipment and machinery installed for traction purposes in the power-station, and of the rolling-stock, and notes are given as to the effect on the overhead wiring of lightning and atmospheric electricity, of bond-resistance, of the impedance of the return rails, of the paths of the return current, and of the effect of the alternating current on telegraphs and telephones. The question of dealing with tunnels is also raised, though there is no tunnel on the electrified section. In the description of the power-station it is shown how the alternating current for the infrequent service is obtained from the existing direct-current generating machinery, and how the heavy traction "peak" loads are arranged to be dealt with from the comparatively low-capacity power-station.

The electrical equipment of the rolling-stock is of two types, respectively, by Messrs. Siemens Brothers' Dynamo Works, Ltd., and the British Westinghouse Electric & Manufacturing Co. The two equipments have been arranged for working from the same master controllers and on the same train. The motors and the contactors are described in detail as regards their more special points. The results of tests of the equipments in their ordinary work on the electrified section, and also in special tests in accordance with the contractors' guarantee, are shown. It is shown that the motor-cars are required to work very similarly to locomotives, and take over daily from steam locomotives trains totalling up to a weight of 190 tons, which is 125 per cent. over the loading specified to the contractors. The Paper goes on to set out the disabilities under which it has been variously alleged single-phase apparatus labours—particularly in respect to its asserted unsuitability for high-schedule-speed, frequent-stop, suburban and inter-urban traffic necessitating high accelerations—and to prove, from the results of special tests, made with a view to ascertaining the accelerating capabilities of the Heysham equipments, that single-phase apparatus is not only equally as capable of working such services as direct-current apparatus, but that the weight of the single-phase trains is only a very small percentage greater than that of corresponding direct-current trains, and that the energy-consumption is appreciably less.

The Paper concludes by giving details of the results in service of the equipments, an indication of the probable cost per train-mile of such service, detailed notes of the mileages accomplished and lost by defects, a note as to the development, cause, results, and steps taken to remedy and obviate such defects, and detailed figures as to the amount of cleaning, repair, and attention required; also, where possible, the mileage life of the various wearing parts, including bows, commutators, brushes, bearings, contactor contacts, wheel-tires, &c.

Comparison of Costs with Steam and Electricity on the Mersey Railway.

The author of the second Paper presents a comparison of the equipment and working-results of the Mersey Railway when worked by steam and by electricity. Owing to many exceptional features connected with this railway, the working-expenses were always very heavy, and as the difficulty of maintaining efficient ventilation made the railway very unpopular with the travelling public, the revenue was insufficient to make a commercial success of the undertaking. The line suffered severely from the strong competition of the ferry service between Liverpool and Birkenhead, which was owned by the Birkenhead Corporation. The question of adopting a different form of traction was under consideration for many years, and finally, in 1900, the company obtained Parliamentary powers to substitute electricity for steam. The work was commenced shortly afterwards, and the electric service was inaugurated in May, 1903. The final change was accomplished in a single night, no mixed passenger service being run.

The traffic conditions call for a train service of 19½ hours per day, with a peak-load for a few hours in the morning to Liverpool, and another peak-load for a few hours in the evening in the reverse direction. During steam working the peak was met by increasing the number of trains in service, and, under electric working, the peaks are met by increasing the number of cars per train, keeping the interval between the trains constant throughout the day. A number of comparisons of the respective train services are made in the Paper, dealing with the weights of trains, mileage, seating-capacity, speed, &c.

The special feature about the electric rolling-stock is the Westinghouse system of electro-pneumatic control. For dealing with the heavy traffic, the trains consist of four- or five-car trains, with a motor-car at each end. After the heavy service is over, the trains are divided about the centre, one motor-car and one trailer only being used for each train unit. In selecting a position for the power-station, the company was exceptionally fortunate in having a site practically at the electrical "centre of gravity" of the system, which permitted of a distribution system being adopted which depended entirely on the conductor rails, without the assistance of any copper feeders, except the short lengths which connect the rails with the power-station. This method of distribution is probably the only one of its kind which has been adopted for heavy traction. The adaptation of the existing permanent way to meet the new system of traction necessitated many alterations being made, practically the whole of the track having to be relaid in order to arrange for the conductor rails being installed. The low-pressure hydraulic lifts at the two deep-level stations were retained for the new service, but the steam-driven pumping-plants were superseded by electrically driven pumps. The speed of the lifts was also accelerated to permit of a one-minute service being maintained at each station. The large steam-driven ventilation plant, which was a very necessary adjunct to the railway when operated by steam, has been superseded by three small electrically driven fans, which cost very little for maintenance, and maintain the atmosphere of the tunnel in a very satisfactory condition.

In order to make a comparison between the working-results of the railway when operated by steam and electricity, three years' working-results under both systems have been analysed, and for each system an average year of steam and of electricity has been arrived at. The working-results are compared on the basis of total cost per annum, cost per train-mile, per ton-mile, and per seat-mile. The costs have been divided under various headings, which make up the total cost of the locomotive and engineering departments. The departments of a railway which are most directly affected by the substitution of electricity for steam are the locomotive and carriage departments, and the tabulated results show that under electric working these costs have been reduced from 0·117d. to 0·089d. per ton-mile. With electric traction, 1lb. of fuel, costing 8s. 9d. per ton, moves 1 ton of load 2·29 miles at an average speed of 22¼ miles per hour; whereas, with steam, the same weight of fuel, costing 16s. per ton, moved the same load 2·21 miles at an average speed of 17¾ miles per hour.

The effect of electric traction on the maintenance of the permanent way has been to reduce the cost of maintenance per ton-mile from 0·0208d. to 0·0089d., or by 0·012d. per ton-mile.

As regards the life of rails under the two systems, the average rolling-load over the track before the rails require renewal is increased from 32 million tons to 47½ million tons.

The substitution of electrically driven pumps for the working of the hydraulic lifts has decreased the cost per lift-mile from 85·2d. to 30·1d., a decrease of 55·1d. per lift-mile.

The effect of electric working on the working-results has been to decrease the cost per ton-mile, as follows: (1) Total cost of working and maintaining the whole of the locomotive and engineering departments from 0·238d. to 0·152d., a decrease of 0·086d. (2) Total costs of the railway, including general charges, &c. (but exclusive of interest on additional capital for electrification), from 0·344d. to 0·24d., a decrease of 0·104d.

Summarised comparative results of the change upon the working and finances of the railway are given in three tables, which show, among other things, that the average speed, including stops, has been increased from 15·6 to 19·9 miles per hour, and the number of ton-miles per annum from 43 to 67 millions, while the total expenses per ton-mile, after allowing interest on additional capital for electric works, have been reduced from 0·344d. to 0·2928d. In the half-year ending June 30th, 1908, the number of passengers carried was more than twice as many as in the last half-year of steam working (ending December 31st, 1902), and more than 2½ times as many season tickets were issued: the seat-miles run per passenger showed a decrease of 30 per

Digitized by Google

cent.; and the pasenger receipts per seat-mile an increase of 26·5 per cent.; while the ratio of expenses to receipts decreased from 95·3 per cent. to 69·8 per cent.

Working Results on the North-Eastern Railway.

The third Paper deals with certain branches of the North-Eastern Railway, which the company decided in 1903 to work by electric traction. They are known as the "Tynemouth Branches," *i.e.*, from Newcastle to Tynemouth direct and by the Riverside Line, and also from Newcastle to Tynemouth *via* Benton and Whitley Bay. The line as electrified was brought into use on July 1st, 1904. It is therefore possible to form some idea of the effect of electric traction and the cost of maintenance. The total length of electrified line, including sidings, is 75 miles, and the average distance between the station stops is 1¼ miles. The current, at a pressure of 600 volts, is taken direct from the conductor rail by shoes fixed on the electric cars, the return current passing through the track rails which are bonded similarly to the conductor rail. The Paper describes the contact shoe, bonding, anchorage for preventing the "creep" of the rails, and the track cable terminals. It also compares the train service under steam and electrical working respectively. Although the train mileage has nearly doubled, the car-mileage and ton-mileage are slightly less under the new conditions. The Paper also deals with the amount of wear on permanent way, which, although greater under electric traction at points and crossings than with steam train working, is only slightly increased on the ordinary running line, either on the straight or on curves. Mention is also made of the methods of inspection of insulators, bonds, and electrical connections, and also the difficulties encountered owing to the presence of snow or ice on the conductor rail, which are overcome by the use of special ice-scrapers fixed on the car. Although the pressure is 600 volts, there has not been a fatal accident due to electric shock to any of the company's employees, and serious injury due to shock has been very exceptional, the men being provided with insulated tools, rubber gloves, and mats for their protection. Fatal accidents through shock which have occurred on the electrified lines have, in all cases, been due to trespass.

The electric cars are of the open corridor type, lighted and heated by electricity, and ample space is provided for the comfort of the passengers. Trains can be made up of two, three, four, or any convenient number of coaches as may be required, up to a length of 550 ft., which is of great advantage. Three electric parcels-vans are used for dealing with the fish traffic between Tynemouth and Newcastle, and also work a service of parcels-trains. These vans are also fitted with end buffers so as to haul ordinary horse-boxes, fish-wagons, carriages, &c., if required.

The electric trains enable much more work to be done at the platforms at the Central Station, Newcastle, than could be accomplished by steam, the work being facilitated by the fact that there are no engines to be attached and detached. They can be discharged and reloaded for a return journey in two minutes, and are all dealt with from three platforms. The economising of platform accommodation is one of the most satisfactory features of electric-train working. Another great advantage is that the signal movements are reduced by one-half. With the steam trains there are four platforms and eight signal operations, but with the electric trains there are only two platforms and four signal operations.

Another important feature, especially for a service of frequent stops, is the high acceleration possible with electric trains. A saving of time is effected without increasing the maximum speed, as will be seen from the following: (1) Time occupied in running round trip from the Central Station to Manors North Station with steam train—68 min. Ditto, with electric trains 58 min. (stopping at all stations). (2) Time occupied in running from the Central Station to Tynemouth Station *via* the Riverside Line with steam trains—35 min. Ditto, with electric trains -29 min. (stopping at all stations). (3) Time occupied in running by express steam train from the Central Station to Monkseaton *via* Wallsend—30 min. Ditto, express electric train - 25 min.

The Paper gives an estimate of the annual cost of renewals, with a table, and concludes by showing that it would have been impossible to carry by the old steam service the number of passengers that are now being conveyed on the Tynemouth lines with the electric service.

DUBLIN LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS

THE opening meeting of the Dublin Local Section of the Institution of Electrical Engineers was held on November 11th, when Prof. W. Brown delivered his inaugural address, which took the form of a lecture on "The Magnetic Testing of Iron." Prof. Brown said that as years passed on and the number of scientific institutions and their branches increased, it was an extremely difficult matter to find a suitable subject for such an address, and he had determined after much thought to frame his address on a subject in which he had been interested for the past fourteen years, viz., the magnetic testing of iron. Although it might, perhaps, be considered a somewhat academical subject to choose, nevertheless it was one of vast importance to all electrical engineers, as the efficiency of all electrical machinery, such as dynamos, transformers, &c., largely depended upon the selection of suitable iron for use in their manufacture.

Prof. Brown then dealt with his subject from an historical and practical standpoint, explaining the principles involved, and describing in great details the various instruments which had been invented from time to time to enable iron samples to be tested quickly and accurately. Many instruments were shown, and some of them were connected up to enable Prof. Brown to demonstrate the manner of their use. The lecture was also copiously illustrated by lantern slides.

Mr. W. Tatlow, in moving a vote of thanks to Prof. Brown, mentioned that he (Prof. Brown) had just succeeded to the Chair of Physics at the Royal College of Science in succession to Prof. Barrett, and congratulated him upon his elevation. The lecture they had just heard was a most valuable one, coming as it did from one who was undoubtedly an authority on the subject.

Mr. W. Brew seconded the motion, which was carried with acclamation, and the proceedings terminated.

THE LATE DR. JOHN HOPKINSON

Gift of Memorial Bust to the Institution

PREVIOUS to the reading of Prof. Kapp's Presidential Address at last Thursday's meeting of the Institution of Electrical Engineers, Prof. Bertram Hopkinson presented to the Institution, on behalf of his mother, a memorial bust of his father, the late Dr. John Hopkinson, by Mr. Hamo Thornycroft.

In making the presentation, Prof. Hopkinson pointed out that whereas the work of a great poet or artist was the best memorial of the man himself, and also a lasting one, it could hardly be said to be the same in the case of a man of science. The work of the latter necessarily resulted only in an addition to general knowledge, and if this additional knowledge was not entirely displaced by some clearer and more definite work to which it had led up, it was certain to be absorbed sooner or later into the whole. For this reason, and in order that something more than the mere name of Hopkinson should be remembered, his mother presented this bust, to be placed in the permanent home of the Institution.

On behalf of the Institution, the president, Mr. W. M. Mordey, expressed the thanks of the Council and members to Mrs. Hopkinson for her gift. He did not fear, he said, that Hopkinson's name would ever be forgotten so long as electrical engineering was practised. Hopkinson was President of the Institution twice, in 1890 and again in 1896. In 1883 he read an important Paper completely developing the theory of the parallel running of A.-C. machines, the only previous Paper on the subject having been one read in 1869 by Dr. Wilde. In 1884 Dr. Hopkinson gave a practical demonstration at the South Foreland Lighthouse. In 1885 he read his Royal Society Paper on "The Magnetisation of Iron." This Paper, said Mr. Mordey, had been the standard ever since with regard to methods in magnetic research. The important Paper on dynamo-electric machinery in conjunction with his brother, Dr. Edward Hopkinson, in 1886, raised the knowledge of the dynamo from chaos to scientific and engineering order, and was followed by another remarkable Paper on the properties of iron at high temperatures. Finally, Mr. Mordey referred to Dr. Hopkinson's patriotism, and the founding, at his instigation, of the Corps of Electrical Engineer Volunteers, which subsequently did such good work in the South African War. The present close connection between the War Office and the Institution might also be traced back to this.

THE NEW INSTITUTION BUILDING

DURING the course of the meeting of the Institution in London on Thursday last, and also at the dinner of the Birmingham Section on Friday, last year's President, Mr. W. M. Mordey, made a statement to the effect that neither the library nor the offices of the Institution would be moved into the recently-acquired building on the Victoria Embankment until next June, as it was not anticipated that the building work would be completed before. It is the reconstruction of the lecture theatre that is delaying matters, and although it would have been possible to occupy the new offices now, there are certain reasons why it will be more expedient to defer the move until the whole building is ready in June.

The first meeting to be held in the new home will therefore be the inaugural meeting of the 1910-11 session.

CORRESPONDENCE

ELECTRIC DRIVING OF TEXTILE FACTORIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—The Report issued by the Bradford Engineering Society on the Electrical Driving of Textile Factories appears to have been accepted in some quarters as being an authoritative pronouncement based on exhaustive tests and backed up by the whole of the Committee. As this is certainly not the case, I venture, as the reader of the Paper which was to some extent the cause of the formation of the Committee, but more particularly as a member of the Committee, to offer some explanation of the actual facts.

First, the Committee were not unanimous, and although I myself dissented from the form of the Report, the Society have not thought fit to publish this fact;

Second, the Report is *not* conclusive, nor are many of the so-styled "conclusions" based on any tests made by the Committee.

The Report speaks of exhaustive tests, but it does not make it clear that the only comparative tests made were those of speed variation, and that of the two tests mentioned—at Dock Ing and Leigh Mills respectively—the latter (which is electrically driven) showed the smaller speed variation.

The statement that in the mechanically driven mill "the amount of cyclical variation was not so great as had been anticipated" is an example of the misleading way in which the Report is worded. It suggests that the Committee were unscientific enough to form a previous opinion on the matter, which was certainly not the case. The majority of the Committee had never seen the mill, and the anticipations referred to were of unknown amount, and existed in the mind of some unknown person. I submit that a vague statement of this kind should have no place in such a Report.

No figures were presented to the Committee on the relative output of mechanically and electrically driven machines; but to say that "no evidence of increased output from electrically driven machines *can* be supplied" is incorrect, and that "the Committee have been unable to obtain any proof based on actual experience" is more—it is misleading. Evidence of increased output due to electrical driving is available from all parts of the world, and I am sure that the statement to the contrary made above has never been formally agreed by the members of the Bradford Committee, nor would it be by any unbiassed person with a knowledge of the results of electrical driving.

Several of the other conclusions are worded in the same curious manner. I will take as example those which state, "Where power is generated on the site, the mechanical losses are less than the electrical," and "Mechanical losses are excessive if the friction load exceeds 30 per cent." These are generalisations which have not even a single test to support them.

If the writer were disposed to generalise from the very large number of tests which he has made in woollen mills, he might with justice disagree with both of the above conclusions, but it is perhaps sufficient to point out that on such vital points as these the Report furnishes conclusions without data—bricks without straw.

For the reasons given above I disassociated myself with the Report, and I much regret that it should have been issued without fuller consideration.

Yorkshire Electric Power Co.
Thornhill, Dewsbury.
November 15, 1909.

I am, Sir,
Yours, &c.,
W. B. WOODHOUSE.

THE INSTITUTION OF CIVIL ENGINEERS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—A full house listened from 8 until 9.20 p.m. on Tuesday night to the Secretary and his Assistant reading in a most capable way three Papers. Amongst the audience were railwaymen who had journeyed from Newcastle, Heysham, and Liverpool, and the writer ventures to think their reason for coming to London was to hear a discussion on these Papers, which everybody really interested had already read, but nothing transpired but the reading.

The Institution supplies to every member who asks for it a copy in advance, and to the personal knowledge of the writer each of the gentlemen referred to had read the Paper before coming to the meeting.

Is there any reason for continuing a practice of reading more than the barest outline of Papers which have been before the members privately in advance of the public meeting? Would it not meet with general approval if Papers were laid on the table and the discussion commenced forthwith? If your columns are open to ventilation of this suggested economy of time, the writer believes you will have benefited a large number of your readers.

London, Nov. 11, 1909.

Yours, &c.,
ASSOC.M.INST.C.E.

LOCAL NOTES

ABERDEEN: *Charge for Tramway Energy.*—The Corporation have applied to the Board of Trade for its approval to the agreement embodying Mr. W. H. Patchell's award as to the price to be paid by the Aberdeen Suburban Tramways Co. for electrical energy. It may be remembered that the company dispute the validity of Mr. Patchell's award, and the consent of the Board of Trade in the manner asked for by the Corporation would have forced the award upon the company. In the circumstances, the Board of Trade have refused to signify their approval of the agreement.

BARNES: *Electrical Exhibition.*—The sub-committee, which was formed last month to consider the advisability of holding an Electrical Exhibition, have reported that, after investigating the matter, they are of the opinion that it was not desirable to proceed with the proposal at the present time.

COLWYN BAY: *Engineer's Salary.* It has been decided to reduce the Borough Electrical Engineer's salary by £30 per annum, for the next six months. The undertaking has recently been reported upon by an independent engineer, and considerable dissatisfaction has been expressed at the financial position.

DERBY: *Extension of Electric Supply Area.*—The Council have confirmed the recent recommendation of the Electric Lighting Committee to apply for an extension of the boundaries for electric supply.

DUBLIN: *Dispute between Corporation and Tram Co.*—A dispute, which will probably lead to a legal action, has arisen between the Corporation and the Dublin United Tramways Co. in respect of the rent which the latter pays for wayleaves for its tramways in the city. In a report upon the matter, the Estate and Finance Committee state that, up to the year 1900, no question arose as to the amount of the annual payment, as the mileage being under twenty miles, the company were liable for the minimum of £10,000 as fixed in an agreement. By the construction in that year of the Ballybough extension, the mileage became in excess of twenty miles, and wayleave became chargeable thereon at £500 per street mile. Since then it appears that no additional payment has been made by the company, in consequence of a difference of opinion as to the meaning of the words "per street mile" in the agreement. The company state that the Corporation wish to charge double the mile rate in the case of crossings where there are four tracks, for instance, and argue that if this is the true construction of the agreement, then where there is only single track half rate should be charged, and that therefore they have paid at too high a rate in the past. The Council claim a balance of £4,209 as due to them.

FRIMLEY: *Electric Lighting.*—The Council are to apply to the Board of Trade for an Electric Lighting Provisional Order.

GLASGOW: *Domestic Electricity.*—The Corporation Electricity Department had a stall at the recent Women's Industrial Exhibition, where they made a speciality of heating and cooking apparatus.

HUDDERSFIELD: *Tramway Track Renewal.*—A dispute having arisen between the Linthwaite Urban District Council and the Corporation as to who should bear the cost of relaying the Corporation tramway track in Linthwaite, the matter was referred to arbitration. The decision is that the whole of the work shall be carried out at the expense of the Linthwaite Council. The estimated cost is £10,000.

Electricity Supply.—In a review of the work of the various departments during the past year, it is stated that the demand for electricity has been considerably more than in the previous year, the number of consumers connected being 302, and total 3,107. The connections in the equivalent of 8-c.p. lamps have risen to the highest point ever touched since the inauguration of the undertaking. Due, however, to the higher efficiency of metal filament lamps, the output was lower than in the previous year. There are 416 motors, at a total of 413 h.p., connected to the single-phase supply.

The Corporation have given notice of their intention to apply for an Electric Lighting Provisional Order for the South Crosland District.

ILKESTON: *Tramway Undertaking.*—At the last meeting of the Council, the chairman of the Tramways Committee stated that the new tramways manager had presented a lengthy report of a most unsatisfactory character. He thought that if things

Digitized by Google

had gone on as they had been going on, the whole plant would have been scrap in another twelve months. The report is to be printed and distributed to the members of the Council.

INDIA: *Electricity Act.*—In connection with the revision of the Indian Electricity Act, which is now under consideration, the Punjab Chamber of Commerce has requested that all owners of property be compelled to allow brackets to be fixed to their buildings for the purpose of carrying overhead wires. They point out that at present in certain districts an arbitrary owner may be instrumental in preventing a whole district from having a supply of electricity.

KINGSWINFORD: *Electric Supply.*—An arbitration took place in London last week between the Council and the Midland Electric Corporation for Power Distribution concerning some matters in dispute regarding the electric lighting of the district by the company.

LIMEHURST: *Electric Lighting.*—In order that the Oldham Corporation may supply electricity to the Council in bulk, an Electric Lighting Provisional Order is to be applied for.

LLANDUDNO: *The Price of Tramway Energy.*—The hearing of the action by the Council against the Llandudno and District Tramways Company, which concerns the interpretation of a clause in the agreement under which the Council supply electricity for the tramways, has been postponed, owing to negotiations which are taking place between the parties.

LONDON: *City of London.*—The City Corporation decided, at a special meeting on Monday, to proceed with the construction of a new bridge across the Thames, with its City outlet at the northern end of St. Paul's Cathedral, at an estimated cost of £1,646,483. The reconstruction of Southwark Bridge to the width of Queen Street Place, at an estimated cost of £261,000, was also decided upon. The question of applying for powers for running tramways over these bridges is under consideration.

County of London Co.'s Mains.—The County of London Co. has appealed to the Board of Trade against the refusal of the City Corporation and the London County Council to sanction the route selected for laying a main to connect their Wandsworth and City Road power-houses. The *City Press* states, however, that an agreement will probably be arrived at as the result of a conference which is shortly to take place.

Marylebone: Street Lighting.—The Electric Supply Committee report that 1,886 of the 1,964 gas lamps under the scheme adopted in March have been changed over at a cost of £5,523. The remaining 78 are estimated to cost £265. The total cost will thus be £5,788, as against the final estimate of £6,886. There still remain 1,385 lamps in streets where at present there are no mains. The price paid to the gas company for these lamps is £5,500. The cost of laying the necessary ducts and putting in mains of sufficient size for the lighting of these remaining lamps (1,385) would be, with ordinary labour, £19,965, or, with "unemployed" labour, £23,420. The cost of altering the lamps themselves for the purpose of electric lighting would be £1,385. The total includes the full cost of the ducts which would be available for supply to private consumers, and the Committee recommend that a loan of £24,000 for 25 years be applied for. The present annual cost of the public lighting affected by the scheme will be maintained.

NEWCASTLE: *Threatened Strike of Tramway Employees.*—The Newcastle & District Tramway Workers' Union have taken up the question of the tramway employees' grievances, and have issued ballot papers asking the men whether, in certain eventualities, they would cease work. The result was announced on Friday, and was in favour of the men ceasing work in the event of their grievances not being met. The Tramways Committee have appointed a sub-committee to meet a deputation from the Tramway Workers' Union next week.

ROTHERHAM: *Electricity and Tramways Undertakings.*—Powers are to be sought for laying feeder and distributing main in the Broom district, and for borrowing £5,000 for main extensions and services. Powers to run railless cars in various districts are also to be sought.

SCOTLAND: *Colliery Power Station Destroyed.*—At a fire which occurred in the winding-engine-house of the Bankton Colliery, Trement, East Lothian, on Monday, the whole of the electrical plant, it is stated, was totally destroyed.

URUGUAY: *Electric Supply.*—The American Consul at Monte Video states that an offer has been made to the Interior Department of Uruguay by some French promoters to establish electric power stations in the interior. The promoters bind themselves to furnish electrical energy for lighting and power to the municipalities as well as to the citizens at a price equal to the lowest price now paid in any of the towns. A concession for 25 years is asked for, after which time the power stations will become the property of the State. It is proposed to start work in the first instance in 18 towns not now provided with electrical energy.

WEST FIFE: *Electric Supply.*—Mr. G. Balfour will apply to the Board of Trade for an Electric Lighting Provisional Order for a portion of West Fife, including the Borough of Lochgelly.

Tramways.—The West Fife Tramways Co. intimate that they will apply to the Board of Trade for an extension of their tramways from Dunfermline to Rosyth.

WINCHESTER: *Electric Light Company's Undertaking.*—The Council have decided to appoint an electrical engineer to inspect the Winchester & District Electric Light & Power Co.'s undertaking, in order to ascertain that the interests of the Council, as the purchasing authority under the company's Order of 1895, are being safeguarded.

YORK: *Construction of Tramways.*—Considerable progress is being made in the construction of of the electric tramway system. A large number of these have been erected, and the feeder cables have been laid along practically the whole of the Fulford route. A good portion of the overhead equipment has also been completed in various parts of the city.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BELFAST.—The recommendations for the improvement of the electrical plant belonging to the Corporation will include provision for an extension to the amount of a 1,500-kw. plant at a cost of about £62,200.

KEIGHLEY.—Application is to be made to the Local Government Board for sanction to borrow £21,000 for extensions.

LONDON: *Shoreditch.*—A new feeder main is to be laid from Whiston Street station to Evelyn Street sub-station.

LOWESTOFT.—A Local Government Board inquiry was held last week concerning a loan of £1,182 for the purposes of the electricity undertaking. It is proposed to instal a new 250-kw. generating set and two chain-grate stokers.

PEMBROKE (Ireland).—Application is to be made to the Local Government Board for a loan of £8,000, made up as follows:—Service cables, £3,136; mains extensions, £1,900; meters, £1,800; fuse boxes, £300; joint and network boxes, £300; coal store and coal handling plant, £500.

SOUTH AFRICA.—The Council of Somerset East (Cape Colony) have appointed an Electric Lighting Committee to inquire into the desirability of undertaking an electric lighting scheme.

SOUTHEND.—A number of extensions of mains are to be carried out, at an estimated expense of about £1,000.

WEDNESBURY.—Application is to be made to the Local Government Board for a loan of £1,750, for prospective expenditure on mains and meters, and £345 in respect of money already spent.

Miscellaneous

AUSTRALIA.—The Melbourne Corporation require 1,250 opalescent arc lamp globes. Particulars from Messrs. Mellwraith, McEacharn & Co. Ppty., Ltd., Billiter Square Buildings, London, E.C., and tenders by November 29th.

LONDON: *London County Council.*—The Highways Committee recommend an expenditure of £2,448 on the purchase of car ploughs for the tramways.

RIO JANEIRO.—Mr. E. D. Trowbridge, the concessionaire for the telephone system of the State of Rio de Janeiro, has been authorised to lay a submarine cable between Rio de Janeiro and Nictheroy.

SOUTH AFRICA.—The East London Municipality have decided to relay their electric tramway track, at an estimated cost of £8,500. The Potchefstroom Council are considering the question of a municipal electric lighting scheme.

The Pretoria Council have under consideration the installation of a tramway system at an estimated cost of £160,000.

SOUTHAMPTON.—About £250 are to be spent on tramway track renewals. The estimated cost of laying down tramways from the Clock Tower to the Northam Toll Bridge is approximately £7,428. Four extra cars will be required, the cost of which is put at £600 each.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.—Schools, Hoxton (£32,650). Builders, W. Johnson & Co., Ltd., Wandsworth Common, S.W.

E.—School, North Woolwich (£9,882). Architect, R. L. Curtis, 11 & 12 Finsbury Square, E.C. Builder, F. J. Coxhead, Bulwer Road, Leytonstone.

S.E.—New grand hall, Camberwell New Road. Architects, F. Matcham & Co., 9 Warwick Court, W.C.

W.—School for girls (£1,350) at L.C.C. Hammersmith School of Arts and Crafts. Architect, T. J. Bailey, L.C.C. Education Committee, Victoria Embankment, E.C.

PROVINCES.

BRISTOL.—School, Alexander Park. Builder, S. Roberts, Plymouth.

Bank premises. Builders, Hayes & Sons, Bristol

Digitized by Google

DERBY.—Boot factory. J. Wilson & Co., Melbourne, Derby. School, Hastings Street. Builder, J. H. Fryer, Derby.

DUBLIN.—The North Dublin Board of Guardians invite tenders for the wiring and fitting of the workhouse buildings, &c. Particulars from Mr. J. L. Lawless, 27 Castlewood Avenue, Rathmines, and tenders to the Clerk, North Brunswick Street, Dublin, by December 1st.

LEEDS.—Tenders are invited by November 23rd for the wiring and fitting of the Kingston Unity Friendly Society's Hall, Union Street, Leeds. Particulars from the Secretary.

MAIDSTONE.—Workshops and offices at Rogers' Wharf (£3,000). County Surveyor, Maidstone.

MALVERN.—Hospital. Builders, Brayer & Sons, Bromsgrove.

NEWCASTLE-ON-TYNE.—Parochial building (£1,685). Architect, A. B. Plummer, Newcastle. Builder, J. Craven, Westgate Road, Newcastle.

WOLVERHAMPTON.—High school. Builder, H. Lovatt, Wolverhampton.

TENDERS RECEIVED AND ACCEPTED

BRAUNTON.—An offer by Messrs. Crompton & Co. to carry out public lighting by electricity at a cost of £52 a year, provided that sufficient shares are taken up to float a local company for the supply of electricity in Braunton, has been accepted.

COLCHESTER.—The tender of Messrs. Crompton & Co., Ltd., for sub-station plant at £374 has been accepted.

CROMER.—An offer by Messrs. Edmundson's Electricity Corporation to substitute Union duplex arc lamps for the present street arc lamps has been accepted. The cost of the lamps will be borne by Messrs. Edmundson's, but the Council have agreed to pay £5 per annum, in addition to the present lighting charges.

GLASGOW.—An order has been placed with Messrs. Hamilton Bros., of Glasgow, for 36 "W.H." motor-control panels for the Glasgow Corporation Main Drainage Scheme, Outfall Works, Shieldhall. The motors are being supplied by Messrs. Wright & Wood, Ltd., of Halifax. We give further particulars on another page.

LONDON: *London County Council.*—The tender of Messrs. Holland & Hannen at £6,827 is recommended for acceptance for the building and architectural work required for the completion of the second portion of the Greenwich generating station.

The tender of Messrs. Johnson & Phillips, Ltd., at £230, has been accepted for the electric lighting of the Buxton Street School, Whitechapel.

RADCLIFFE.—The tender of Messrs. Callender's Cable & Construction Co., Ltd., has been accepted for the supply of low tension three-core lead-sheathed cable, and also for armoured cable.

TORQUAY.—The Council have accepted an offer by the Underfeed Stoker Co. for the installation of mechanical stokers, &c., at £927. It is estimated that an annual saving of £290 in works costs will be made. The initial cost of the apparatus is to be charged to revenue.

The following are among recent orders received by Messrs. Sanders, Rehders & Co., Ltd., 108 Fenchurch Street, London:—East London (S.A.) Corporation: One "Sarco" combustion (CO_2) recorder, Type B, and four "Sarco" dial draught gauges. Sydney (N.S.W.) Corporation: Repeat order for five "Sarco" combustion (CO_2) recorders, Type B (three machines, Type A, have been in use here for some years). Adelaide Tramway Trust: One "Sarco" combustion recorder, Type B; seven "Sarco" dial draught gauges; two dozen "Sarco" pipe thermometers; two dozen "Sarco" high-temperature stem thermometers; one steam pressure gauge and one hand gas-testing set. Melbourne Electric Supply Co., Ltd.: Four "Sarco" dial draught gauges.

Proposed Increase in the French Import Duties on Metal Filament Lamps.—The proposed alterations in the French tariff are said to include an increase in the duty imposed on imported metal filament lamps. The figure, which is now 350 francs per 100 kg., is to be raised to 500 francs per 100 kg. A correspondent to the *Electrotechnischer Anzeiger* asserts that if this becomes law, the German manufacturers will establish branch works in France, and comments on the fact that the industry is flourishing in Germany in spite of the very low duty of 80 marks per 100 kg.

Alleged Death from Electric Shock.—An inquest was held last week concerning the death of a car conductor on the Metropolitan District Railway, who was found dead on the floor of the motor room of an electric train. The driver of the train stated that one of the cables under the car was found to be on fire, and that he asked the deceased to get the passengers out with a view to shunting the train on to a siding. Shortly afterwards he was found unconscious on the floor of the driver's cab. Evidence was given by Dr. Parsons, of St. Mary's Hospital, who stated that he could not account for the death except from electric shock. The inquest was adjourned for expert evidence.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 10s. to £61 10s. per ton (last week, £60 to £60 10s.).

THE LANCASHIRE DYNAMO & MOTOR CO.—This firm have sent a representative to Canada, and have opened a permanent office at 109 Peterkin Buildings, Toronto, in order to deal with the large amount of business which they have in hand in Canada at the present time.

BANKRUPTCIES, LIQUIDATIONS, WINDINGS-UP, &c.—Mr. S. E. Smith, electrical engineer, 271 High Street, Lincoln, has been adjudicated bankrupt.

The last day for receiving proofs in the bankruptcy of W. T. Harris, 460 Commercial Road, Portsmouth, is November 22nd. The trustee is Mr. E. W. Whittaker, 3 Portland Street, Southampton.

A first dividend of 4s. in the £ will be paid at the offices of Messrs. Joscelyne, Miles & Co., 28 King Street, Cheapside, London, on and after November 22nd, in the bankruptcy of J. S. Cunnington & H. P. Allison, electrical engineers and contractors, 7 Great Newport Street, London.

The public examination of E. A. Brandon, trading as E. A. Brandon & Co., 33 Devonshire Chambers, Bishopsgate Street Without, E.C., electrical and mechanical agent and factor, took place at the London Bankruptcy Court on November 10th. The statement of affairs showed a deficiency of £1,128 16s. 10d., there being practically no assets. Debtor attributed his failure to bad trade. Among the trade creditors are:—Armorduct Manufacturing Co., Ltd., Farringdon Avenue, London, E.C., £63 7s. 11d.; Electrical Co., Ltd., Charing Cross Road, W.C., £39 3s. 8d.; Foster Arc Lamps & Engineering Co., Ltd., Wimbledon, S.W.; £10 13s.; G. Gilkes & Co., Ltd., Canal Iron Works, Kendal, £14 10s.; Hawkins, Morris, Ltd., Electrical Engineers, Dagenham, Essex, £45; Sloan Electrical Co., Ltd., Fore Street Avenue, E.C., £39 7s. 3d.; John Spencer & Co., Ltd., Globe Tube Works, Wednesbury, £64 13s.; International Electric Co., Kilburn, £88; Tubes, Ltd., Birmingham, £107 8s. 8d.

A second and final dividend of 11½d. in the £1 is announced in the bankruptcy of Arnold Roberts, electrical engineer, 21 North Parade, Bradford. The dividend is payable at the offices of Mr. J. H. Haley, 29 Tyrrel Street, Bradford.

The petition of Messrs. Dick, Kerr & Co., and Messrs. A. Schonfield & Co., for the compulsory winding-up of the British Aluminium Co., Ltd., has been postponed until the next sitting.

DOWSING RADIATOR LAMPS.—We regret that on page 951 of our issue of November 4th, the address of the Dowsing Radiant Heat Co., Ltd., was given incorrectly. It should be 24 Budge Row, E.C.

BOBY WATER SOFTENERS.—The Jury of the Imperial International Exhibition, Shepherd's Bush, have awarded Mr. W. Boby a gold medal for his water softener exhibited there, and which supplied softened water during the whole time that the Exhibition was open. We are informed that this is the first and only instance in which a British exhibition has made an award for excellence in water softening appliances.

Music-Hall Electricity.—Mr. Walford Bodie, on Saturday, paid into Court the sum of £1,000, for which judgment was entered against him in the recent action by a pupil of his in respect to a contract. Notice of appeal has also been entered. Glasgow medical students have been the cause of the premature withdrawal of Bodie's name from the programme of the Coliseum there. An attempt was made to rush the stage last week, and it is alleged that Bodie was seriously injured in the *mêlée*. In consequence, a telegram was received in London on Monday, stating that Bodie was too ill to appear at the Paragon and Canterbury Music Halls, with the proprietors of which he had a contract. In spite of the assurance that Bodie would not appear, some disturbance on the part of medical students took place at the Canterbury Music Hall on Monday, and several arrests were made.

L.C.C. Tramway Conciliation Boards.—With reference to the decision to establish Conciliation Boards for the settlement of questions affecting employees of the London County Council Tramways, the Highways Committee have nominated the Council's representatives. The Boards will be named as follows:—(1) Traffic; (2) Rolling stock; (3) Electrical; (4) Permanent way and buildings. There will also be a Central Board. The nominations are as follows:—No. 1: Mr. A. Shirley Benn, Capt. the Hon. FitzRoy Hemphill, Mr. H. V. Rowe, and the Lord Alexander Thynne and the chief officer of tramways and the tramways traffic manager; No. 2: Mr. W. J. Squires, Mr. T. C. E. Goff, Mr. W. Hunt, and Mr. Henry Ward, and the chief officer of tramways and the tramways rolling stock superintendent; No. 3: Mr. W. Whitaker Thompson and the chief officer of tramways and the tramways electrical engineer; No. 4: Mr. F. Hall and the chief officer of tramways and the tramways permanent way engineer; Central Board: the deputy chairman of the Council, Mr. A. Shirley Benn, Mr. W. J. Squires, Mr. F. Hall, and Mr. W. Whitaker Thompson, and the chief officer of tramways. The employees have the right to nominate an equal number of representatives.

COMPANIES' MEETINGS AND REPORTS

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS.—The report for the year to October 31st shows a profit of £1.522 against £1,479 in the previous year. There is also a balance of £80 brought forward. After meeting 5 per cent. preference dividends, a balance of £303 is carried forward.

At the annual meeting on Tuesday, the report and accounts were adopted.

EASTERN TELEGRAPH CO.—At the annual meeting last week, the report and accounts given in our issue for November 4th were adopted.

WESTERN TELEGRAPH CO.—At the annual general meeting last week, the report and accounts were adopted. Sir John Wolfe Barry, who presided, stated that satisfactory arrangements had been made with the Argentine Government for the laying of a direct cable by the company from Buenos Aires to Ascension Island, where it would join the existing main line to Europe. It was hoped that the cable would be laid and working next year. Negotiations were also in progress for the laying of a direct cable from Ascension Island to Rio Janeiro.

EASTERN EXTENSION: AUSTRALASIA & CHINA TELEGRAPH CO.—At the annual meeting last week, the report and accounts given in our issue for November 4th were adopted. Sir John Wolfe Barry, who presided, stated that there were signs of recovery of trade in the Far East, which he hoped would stop the continuance of the decrease of revenue shown by the present accounts.

RICHARDSONS, WESTGARTH, & CO.—After meeting debenture interest and other preferential charges, there is a loss on the working for the year to August 25th of £17,326. There is now a total debit balance of £26,703.

Manchester Section, I.E.E., Students' Meeting.—The opening meeting of the Manchester Students' Section of the Institution of Electrical Engineers took the form of a supper, held on Tuesday, November 9th, at the Mosley Hotel, Manchester. Mr. C. S. Richards, vice-chairman, presided, and about 90 members and visitors were present. A very successful smoking concert concluded the proceedings.

The Electro Peat Coal Co.—In the Court of Appeal on Tuesday, Mr. J. C. Barker appealed against the decision of Mr. Justice Lawrence in the action in which he sued the Earl of Mayo, a Mr. Simpson, and others for damages for alleged fraudulent misrepresentation, whereby he was induced to subscribe for 2,000 shares in the Electro Peat Coal Co. In the case of the action against Mr. Simpson, a judgment was entered for Mr. Barker, but in the case of the other defendants, he lost the action. Mr. Simpson asked the Court of Appeal to set aside the judgment of Mr. Justice Lawrence in respect of the Earl of Mayo, and the other defendants (exclusive of Mr. Simpson), but the application was dismissed.

Telegraph Traffic.—A series of breakdowns have occurred in the West Indies. The island of Jamaica was entirely isolated on Sunday last, in consequence, no doubt, of the washing away of the land connections between the Cable Houses and Kingston. This was followed by the breaking of the cables running between Jamaica and Puerto Rico, and also between Turk's Island and Jamaica. It would appear that a hurricane had struck Hayti and San Domingo, for the landline from Puerto Plata to San Domingo was broken, and the cables from Puerto Plata to Martinique, Cape Haitien and Mole St. Nicholas ceased working on the 7th inst. The effect of all these disasters is shortly this. Telegrams can now only be sent to Jamaica, Kingston having been again in telegraphic touch since the 14th inst., but all the islands beyond Jamaica, including Puerto Rico, are cut off. We do not, however, believe that the interruption will be of long duration, as the West India and Panama Telegraph Company have a cable repairing steamer on the ground, and the Direct West India Telegraph Company will, as usual, lose no time in repairing their breaks.—On the 9th inst., the land line between Saigon and Tonkin was restored, and on the same day the cable between Tourane and Amoy was again on the active list.—The 10th inst. saw a break in the Cochin China-Tonkin land line.—On the 11th inst., the cable between Sitka and Valdez (Alaska) was again working, while on the 14th several breaks occurred in the lines to Adana, Alep, and Sivas Diarbekir, as well as in the Elarich and Hanekine routes.—On the same day the line between Saigon nd Bangkok suffered an interruption, but was quickly restored to working order, together with the cable between Balikpapan and Kwandang.—Some delay occurs to messages to Syria and Irak, owing to two of the Anglo-German cables being broken. Delay has also to be allowed for on Continental telegrams. Difficulty is being experienced in repairs owing to the fishing fleet being on the grounds where the breaks have occurred.—The new cable of the Western Telegraph Company, to be laid from the Argentine Republic to Europe, via Ascension, will cost about £1,000,000, and it is to be laid by October, 1910.—The Continental Telegraph and Telephone Company has been incorporated in New Jersey with a capital of $50,000,000, to take over independent telegraph lines. It is stated to be connected with another company seeking an entrance into New York.

MISCELLANEOUS CITY NOTES

AUCKLAND ELECTRIC TRAMWAYS CO.—An interim dividend of 6 per cent., less income tax, is recommended on the ordinary shares for the past half-year.

ALUMINIUM CORPORATION.—At meetings on Wednesday last week of the unsecured creditors whose claims amount to over £10, the participating preference shareholders, and the ordinary shareholders, it was decided to consent to the registration of a new company, viz., Aluminium Corporation, Ltd. The majority of the creditors have agreed to accept seven per cent. preference shares to the full amount of their claims. The offer on behalf of Messrs. Wernher, Beit & Co., to purchase the undertaking for £80,000, has been withdrawn.

PUEBLA TRAMWAY LIGHT & POWER CO.—Dr. F. S. Pearson and Mr. H. M. Hubbard have resigned from the Board.

NEW PUBLICATIONS

Deinhardt-Schlomann Series of Technical Dictionaries. Vol. V.: Railway Construction and Operation. (London: Archibald Constable & Co.) 12s.

"First Stage Sound, Light, and Heat." By R. W. Stewart. Second edition. (London: University Tutorial Press.) 2s.

Congress of Radiology and Electricity.—An International Congress on Radiology and Electricity will take place in Brussels on September 6th, 7th, and 8th, 1910. The Congress will be divided into three sections, and communications regarding it may be addressed to Prof. Rutherford, or Dr. W. Makower, at the Manchester University.

Wireless Telegraphy.—It is stated that Colonel C. C. Wilson, president of the United Wireless Telegraph Co., has arrived in London with the object of laying before the Postmaster-General a scheme for establishing a number of wireless telegraph stations in England. It is proposed to use these for inland as well as ocean purposes.

X-Ray Dermatitis.—We regret to learn that it has been found necessary for Mr. H. W. Cox to have his right arm amputated above the elbow, owing to X-ray dermatitis. Despite the amputation of three fingers of the right hand early in the year, the disease continued to spread up the arm, and the operation just performed was found to be necessary.

Tramway Companies and Gas Mains.—A case of some interest to tramway authorities was decided in the Appeal Court last week. The Bristol Tramways and Carriage Co. appealed against the decision of an arbitrator (subsequently confirmed by Mr. Justice Phillimore), in which they were condemned to pay certain sums to the Bristol Gas Company for extra expense which the latter were put to between February, 1905, and December, 1906, in altering and connecting service pipes, owing to the existence of the tramways over the mains. The claim was made under Section 32 of the Tramways Act, 1870, the proviso to which reads as follows:—"Provided that any additional expense imposed upon them [gas or water companies] by reason of the existence of the tramway in any road or place where any such mains, pipes, tubes, wires, or apparatus shall have been laid before the construction of such tramway shall be borne by the promoters." The tramway company argued that the works did not come within the section, inasmuch as it was not necessary for them to give any superintendence to the works, and that therefore the nature of the works carried out could not be such as to involve exceptional expense on the part of the gas company. The Appeal Court, however, dismissed the Tramway Co.'s appeal. The sum involved is £115 18s.

Testing of Continuous and Alternating Current Machinery.—Mr. J. W. Rogers read a Paper last Thursday on the above subject before the Rugby Engineering Society, in which he gave an outline of the most usual tests carried out in the manufacturer's testing room. These may be classified under two distinct heads, viz., Experimental and Commercial. Experimental tests are made on all machines of new type for obtaining information with reference to their performance under working conditions, and also to compare the actual with the anticipated performance. The tests required for this purpose are those of insulation, rating and efficiency. As is well known, the rating of a machine is determined by heating, drop in voltage or speed, or commutation; a knowledge of these three quantities being obtained from temperature, regulation, and commutation tests respectively, under various conditions of loads. As regards the efficiency this may be obtained from the relation between input and output, or by calculation of the copper, iron, friction, and windage losses, as determined by the resistance, and iron loss and friction tests respectively. Commercial tests are made chiefly to locate faults in manufacture due to defective material, bad workmanship, faulty assembling, or similar causes. Any defect in the iron circuit of a machine would certainly show up in the saturation and temperature tests in the form of excessive iron loss at normal excitation, and excessive temperature rise of the iron circuit. Generally speaking, the commercial tests for machines of moderate output are iron loss, saturation and friction; temperature run at full load; insulation, and overload and commutation test.

WIMBLEDON ELECTRICAL EXHIBITION

ON Monday last an exhibition of electrical accessories, and particularly of domestic appliances, was opened at the Latimer Road Baths, Wimbledon, and will remain open until Saturday. The exhibition has been organised by the Electricity Department of the Borough of Wimbledon, and comprises some twenty-five stands.

The largest exhibit is that of Messrs. Siemens Bros. & Co., Ltd., who have a collection of accessories exactly similar to that shown at Shoreditch, except that, the supply being alternating current, opportunity is taken of displaying transformers and small A.-C. motors in operation. An earthed outer wiring installation on the O.S. system supplied from a double-winding transformer is also exhibited. An attractive display has been arranged by Messrs. Stegmann & Co. (Brighton Railway Approach, Clapham Junction, S.W.). A fine collection of electric light fittings, a battery-charging board for small country-house installations, and a "Bruston" automatic transformer switch (ELECTRICAL ENGINEERING, May 20th, page 462) are among the items on this stand. The Simplex heating and cooking apparatus, and a comprehensive array of other electrical domestic appliances, are to be seen on the stand of Messrs. Rashleigh Phipps & Co. (147 Oxford Street, W.), who also show their kaleidoscopic sign The British Vacuum Cleaner Co., Ltd. (Parson's Green Lane, S.W.), exhibit a number of electrically-driven rotary vacuum-cleaning sets; and "Daisy" (bellows type) vacuum cleaners with electric drive are shown by Messrs. Wallach Bros., Ltd. (Royal London House, Finsbury Square, E.C.).

A device exhibited for the first time is an electric geyser on the "Bastian" quartz principle, to be seen on the stand of Messrs. Thomas L. Scott & Co., Ltd. (28 Martin's Lane, Cannon Street, E.C.). A quartz tube containing a heating spiral is enclosed in a metal tube, and this is inserted in a tube of considerably larger diameter. The water flows along the annular space between the two tubes. Two such units are connected in series in the apparatus on view. Among the other exhibits are some electrically-driven pumps shown by the Worthington Pump Co., Ltd. (153 Queen Victoria Street, E.C.); a number of different makes of electric radiators; electric light baths, massage apparatus, and heating pads shown by the Regent Electric Co., Ltd. (52 Regent Street, Piccadilly Circus); electric candle fittings of the pattern made by the Lux Candle Co., Ltd. (240 High Holborn, W.C.). The Foster Arc Lamp & Engineering Co., Ltd. (Worple Road, Wimbledon, S.W.), have several examples of flame and enclosed arc lamps, "Foster" metal filament lamps, the "Foster" automatic transformer switch, and the neat little bell transformers manufactured by this firm. Two examples of the "Therol" electric water-heater are exhibited by Messrs. Spagnoletti, Ltd. (Goldhawk Works, Goldhawk Road, W.), and Messrs Purcell & Nobbs (87 Cleveland Street, Fitzroy Square, W.) have several patterns of their "Electroyl" radiators on view. B.T.-H. metal filament lamps, heating and cooking apparatus are shown by A. How & Co. (9 St. George's Road, Wimbledon, S.W.), and an electric piano is exhibited by the Harper Electric Piano Co., Ltd. (258 Holloway Road, N.).

Glasgow Main Drainage Scheme.—An order has been placed with Messrs. Hamilton Bros., 19 Waterloo Street, Glasgow, for 36 "W.H." motor-control panels for the Glasgow Corporation Main Drainage System, Outfall Works, Shieldhall, Glasgow. Each panel consists of slate 1¼ in. thick, having ammeter, ironclad switch, push-button, and "W.H." ironclad motor starter mounted thereon. The apparatus on several of the panels has to be damp, dust, and gas proof, and all the "W.H." starters are fitted with hinged covers, no asbestos being used in their construction. This installation of motor panels is, we believe, one of the largest in this country, and it is interesting to note that all the apparatus is of British manufacture throughout, being made at Messrs. Hamilton's Edinburgh works.

Telephones in Ireland.—In answer to a question in the House of Lords last week regarding main telephone lines in Ireland, and the possiblility of their extension, Lord Denman said that the main line telephones in Ireland were as follows:—From Dublin northwards to Belfast and Londonderry, with exchanges at the principal intermediate towns; from Dublin southwards (1) to Maryborough, Mallow, and Cork; and (2) to Wicklow and Wexford; from Belfast lines ran westward to (1) Magherafelt; (2) Omagh and Enniskillen; and (3) Armagh and Monaghan. From Maryborough a line ran north to Tullamore and Clara, and south to Kilkenny. A long cross-country line ran from Ennis and Limerick to Tipperary, Clonmel, Waterford, and Wexford; and another from Tralee and Killarney to Mallow and Fermoy. The principal extensions in prospect were (1) from Enniskillen to Sligo; (2) to Mullingar, Athlone, and ultimately to Galway; (3) to Clones and Cavan. Those extensions could only be carried out if sufficient local support and guarantees were obtained, and the Postmaster-General was corresponding on the subject with the local authorities and others interested.

VENNER SIGNS AND CREDENDA CONDUITS

AT a recent visit to Birmingham we called at the Credenda Conduits Company's new works in Chester Street, Aston, and we were shown the latest developments in the Venner signs which the company manufacture. These signs are made up of small glass spheres, set in the cover of a metal box, in which one or more electric lamps are placed. Owing to the shape of the glass beads, a very brilliant effect is obtained with only one or two lamps in the box for each letter, and the sign has the additional advantage that it is equally brilliant when looked at even at a fairly sharp angle. For ordinary signs one foot in depth, a single 16-c.p. lamp is quite sufficient for each letter, and for two-feet signs two 50-c.p. lamps give an exceedingly bright result. In a modified pattern, which is now being perfected, an extremely beautiful effect is produced by using three lamps, coloured red, green, and blue, inside the sign. Each bead combines the three colours; its appearance is almost an imitation of an opal, and the colours blend differently as one moves past the sign acording to the angle it is looked at.

The new works of the Credenda Conduits Co. are situated at the corner of Chester Street and Avenue Road in Aston (Birmingham), and are larger, better lighted, and in every way more convenient than the old works of the company, for executing the large orders they now have in hand both for "Credenda" conduits and for the Venner signs. They are also near to the works of Tubes, Ltd., the parent company, which supply the tubes for the Credenda conduits.

A Supply Company's Show-rooms.—The County of London Electric Supply Co., Ltd., has opened additional show-rooms at 206 Upper Richmond Road, in order to afford the residents of Putney and district an opportunity of inspecting the latest improvements in lighting, heating, and cooking by electricity. The advantage to consumers (and to non-consumers) in the district in being able to obtain first-hand, and in a place readily accessible, full information on all matters connected with electric supply is considerable. The show-rooms are in an excellent position in a busy thoroughfare, and everything inside and out has been designed and thought out in a very effective manner in order to display the artistic possibilities of electric light. For instance, the drawing-room aspect is carried out with moulded panelling in green and white, while the dining-room aspect is in the best style of oak. The fittings in each case are in keeping with the designs, and the whole effect is extremely pleasing to the eye. In the window facing the street various exhibits are shown, and these will be varied constantly. At present the electric radiator in every design is tastefully displayed, and later will be shown an electrically-lighted dining-table. Various cooking and heating appliances are on view. The latest types of metallic filament and carbon lamps, electric radiators, irons, kettles, grills, and everything that interests the good housewife, especially in the way of labour-saving devices, can be seen and tried. The show-rooms are situated in a central position, and have been designed throughout with a view to demonstrating that a tasteful installation can be put in at quite a moderate cost by a judicious selection and under expert advice. No one knows the requirements of the consumers better than the company supplying them, and the main object of the company in making this departure is to assist the consumers in obtaining the fullest information and advice in all things electrical. The district supplied by the County of London Electric Supply Co., Ltd., covers fifty-four square miles, and embraces all classes of users of electricity, so the company is therefore in the unique position of being able to advise upon installations of every kind.

Reduction of Iron Ore in the Electric Furnace.—According to the Stockholm correspondent of the *Daily News*, a union of Swedish ironworks, the Jernkontoret, has decided to start a small works at Trollhätten for the commercial reduction of iron ore in electric furnaces. A sum of £25,000 has been raised for the experiment, and the furnaces will be of the pattern developed by the engineers Gronwall, Lindblad, and Stalhane, and manufactured by the Elektrometall Aktiebolaget, of Ludvika. The following description of the furnace is from the same source:—The furnace is very similar in design to an ordinary blast furnace, in which the tuyères are replaced by electrodes. The height is about 25 ft., and the shaft is 18 ft. high. The melting chamber, containing the electrodes, is about 7 ft. high. The isolation of the descending charge from the lining at the point the electrode enters the furnace is said to prevent the destruction of the lining. As compared with the charcoal blast furnace, the comparative cost of pig-iron per short ton is stated to be 8·56 sterling against 10·10 sterling. A recent experiment showed that there had been produced during 1,903 hours' running 28 tons of iron, containing from 0·95 to 3·09 per cent. of carbon. In the manufacture there were used: Ore, 442 tons; lime, 24 tons; coke, 41 tons; charcoal, 58 tons; electrodes, 6·5 tons; and the current consumed was 891,623 kw.-hrs. The efficiency of the furnace would be much higher if the considerable loss of heat by cooling water and radiation could be reduced. This loss appeared to be about 30 per cent.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 11th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications. Names in italics indicate communicators of inventions from abroad.

23,328/08. **Portable Pumping Plant.** W. A. STEVENS. A pump, direct coupled to an electric motor, is mounted on a two-wheeled carriage, which acts as a trailer to a petrol-electric vehicle which supplies power through a flexible cable to the motor. The trailer also has a reel of hose pipe, and can be detached from the petrol-electric vehicle, and wheeled manually to a suitable position. The main vehicle may contain a battery instead of a generating set. Two claims, two figures.

24,594/08. **Electrolytic Apparatus.** J. BILLITER. In an electrolytic vat, stratification due to different specific weights is utilised for the purpose of separating the products at the anode and cathode. The electrolyte near the upper electrodes is heated from above by steam or by heating pipes, and the fresh electrolyte is supplied at the hottest parts of the bath in order to increase the velocity of diffusion of the ions. The electrode chamber below the horizontal diaphragm is fed with the heavy solution which is enriched with the product of electrolysis at the lower electrodes. Three claims, one figure.

27,213/08. **Thermal "Flashing" Switch.** G. SWEETSER. In order to obtain a quick make and break with thermal and other automatic switches, contact is made through a thin bowed metal plate sprung into an internally grooved opening in a metal bracket. The plate is snapped backwards and forwards across its central position by an expansion rod or a bi-metallic strip acting on the buckled plate through a lever. A suitable construction is described. Two claims, five figures.

7,092/09. **Manufacture of Metal Filaments.** W. HEINRICH. A binding agent for forming filaments without carbon, comprises 5 parts of pure sulphur and 6 parts of dry amorphous phosphorous. The mixture is heated, and a dark substance liquid at 200° C. is obtained. Three parts of this substance are mixed with 15 parts of tungsten or other metal powder, and the product squirted into filaments. The greater part of the binding agent is removed by heating the filaments in a vacuum at 450° C., but a metal-phosphide or sulphide is formed which holds the filament together until it is sintered. This last process is carried out in a vacuum at 1,000° C. or more, and the sulphide and phosphide are reduced, leaving pure metal. One claim.

14,239/09. **Telephone Exchange Connections.** SIEMENS BROS. & Co. (*Siemens & Halske Akt.-Ges.*). In order to prevent double connections, a device to inform the exchange clerk that a subscriber is already engaged, and to prevent the calling of the engaged subscriber, is employed. This comprises a relay which is not brought into the circuit of the plug lead until the connecting switch is operated. When the connecting plug is inserted in the jack of an engaged subscriber, the relay receives current through the socket of the jack. It may be caused to prevent double connection by interrupting the plug cord leads or the calling circuit, and to inform the clerk by connecting his receiver to a buzzer. Three claims, two figures.

17,370/09. **Control of A.-C. Commutator Motors.** BRITISH THOMSON HOUSTON Co. (*Allgemeine Elektricitäts Ges.*). Large A.-C. commutator motors are started up as asynchronous motors, and when a certain speed is reached, the connections are changed and the machines run as commutator motors. By this means efficient regulation of the speed for 20 per cent. above or below the synchronous speed can be obtained. At starting, the commutator brushes are raised, and a resistance connected in the rotor circuit through slip-rings is gradually cut out. When the rotor resistance is short-circuited, the brushes are placed on the commutator. If starting is effected by means of an auto-transformer in the primary circuit, no slip-ring brushes are necessary, but a device for short-circuiting the armature as a three phase rotor must be used. The short-circuit can be opened and the brushes placed on the commutator automatically by a centrifugal device. Two claims, one figure.

Opposition to Grant of Patents

8,104 08. **Filaments of Refractory Oxides.** G. MICHAUD and E. DELASSON. The opposition to the grant of this patent has been unsuccessful. It covers a composition of 92 per cent. thorium oxide and small percentages of the oxides of aluminium, cerium, glucinum, and chromium. A method of manufacturing filaments by passing a thread of the paste through oxy-hydrogen flames and an electric muffle-furnace is also described. The filaments can be brought to incandescence in the atmosphere by either gas or electricity.

9,365/05. **Heat Accumulator.** C. NOTHOHM and O. ESTNER. A grant has been allowed on this application in spite of opposition. The specification was abstracted in ELECTRICAL ENGINEERING, July 1st, 1909, and describes an apparatus for converting an intermittent supply of exhaust steam into a continuous supply at a lower pressure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: JIMAR and VON DREGER [Prevention of flickering] 1,541/09.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: WITZENMANN [Machines for armouring cables] 3,257/09.

Dynamos, Motors, and Transformers: SOC. ANON. D'OUGREE-MARIHAYE and COURTOY [Control of rolling-mill and winding motors] 3,588/09.

Electric Ignition: SCHNEIDER [Contact-breakers] 17,436/09.

Electrometallurgy and Electrochemistry: BENKÖ [Primary batteries] 28,290/08; CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE GES. [Production of hydrogen] 21,032/09.

Instruments and Meters: THORPE [Electrolytic meters] 28,561/08.

Switchgear, Fuses, and Fittings: FIELD and FERRANTI, LTD. [Switchgear] 23,515/08; BAYLY [Detachable lock for bayonet lamp-holders] 26,205/08; BAZELL and VERNEY [Ceiling roses] 27,729/08; VERITYS, LTD., and PIPKIN [Regulating switch] 28,092/08; BAERLOCHER [Motor controller] 28,351/08; THORPE [Electrolytic devices] 28,561/08; SUTER [Lamp fittings] 430/09; RICHTER [Time switches] 2,605/09; CUBITT [Switchgear] 7,113/09; DRAULT [Switch] 9,502/09; LAMME [Controllers for polyphase motors] 14,579/09.

Telephony and Telegraphy: FESSENDEN [Wireless systems] 20,005/08; HILDEBRAND [Automatic telephone exchange] 23,888/08; CHAMBERS [Wireless systems] 2,330/09; CONNER [Telephone switchboard lamp jacks] 4,630/09; WHALLEY [Indicator] 5,040/09; CLARK [Telephone receivers] 6,525/09; PICKARD [Wireless receiver] 10,772/09.

Traction: SCHUITE [Hanger for trolley wires] 22,681/08; SCHOLLENBERGER [Trolley wheel] 22,951/08; DURTNALL [Traction system] 23,396/08; KEIL [Signalling] 10,160/09; BUJON and COMPAGNIE DE SIGNAUX ELECTRIQUES POUR CHEMINS DE FER [Signalling] 15,863/09; KREBS and G. KREBS & Co. [Trolley wheels] 15,895/09.

Miscellaneous: MURDAY [Master clock] 22,819/08; DURTNALL [Propulsion of ships] 23,396/08; GREEN and DAIMLER MOTOR Co. (1904) [Electrically-operated clutches] 695/09; NEALE and POWELL [Secondary clocks] 3,437/09; HOPWOOD [Boiler alarms] 14,049/09; WHYTE [Mariners' compasses] 20,537/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: ALLGEMEINE ELEKTRICITÄTS GES. [D.-C. rotary transformers] 24,306/09.

Miscellaneous: MENTEYNE and DEGAILLE [Fire-alarm] 10,569/09; SIEMENS & HALSKE AKT.-GES. [Fire-alarm system] 24,185/09.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distribution Systems, &c.: J. V. JOHNSON (*Hartmann & Braun Akt.-Ges.*) [Junction boxes] 16,837/04.

Dynamos, &c.: E. GAUD [Brush-holder] 16,485/02.

Electric Ignition: F. RENDER [Blasting fuse] 15,222/05; F. J. SCOTCHMER [Sparking-plug] 15,242/05.

Electrometallurgy & Electrochemistry: T. PARKER [Production of phosphorus] 16,862/02; C. D. ABEL (*Siemens & Halske Akt.-Ges.*) [Electrolytic production of zinc] 16,396/04.

Heating & Cooking: ELECTRIC EQUIPMENT AND SECURITIES, LTD. [Resistance material] 16,422/04; C. RUZICKA [Resistance material] 15,390/05.

Storage Batteries: W. GARDINER and C. P. STRINGFIELD [Plates] 15,257/05.

Switchgear, &c.: H. H. LAKE (*General Electric Co., U.S.A.*) [Reverse-current and overload A.-C. circuit-breaker] 16,906/02.

Telephony & Telegraphy: W. SCHÜTZ [Glass telegraph poles] 16,487/03; R. WOLTERS [Transmitting key] 16,578/04; BRITISH THOMSON HOUSTON Co. (*General Electric Co., U.S.A.*) [Duplex telephone system] 15,196/05; A. MEYER [Telephone call register] 15,289/05; S. F. JONES [Duplex telegraphy] 15,298-9/05; H. OPPENHEIMER (*Akt.-Ges. Mix. & Genest.*) [C.-B. telephone systems] 16,455/05.

Traction: E. DE PASS (*M. Johannet and G. Dupont*) [Petrol-electric system] 16,433/96; O. G. BOLITHO [Track signalling] 13,522/00; BRITISH THOMSON HOUSTON Co. (*F. E. Case, U.S.A.*) [Train control system] 15,190/01; A. J. BOULT (*Soc. Anon. d'Electricité et d'Automobiles Mors*) [Control of automobiles] 15,349/01; SIEMENS BROS. & Co. (*Siemens & Halske Akt.-Ges.*) [Safety device for trolley wires] 15,368/01; R. BROWN [Surface-contact system] 15,252/05.

Miscellaneous: SIEMENS BROS. & Co. (*Siemens & Halske Akt.-Ges.*) [A.-C. signalling apparatus] 16,450/05.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** *weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

The electric service on the South London line, which is to be called the South London Elevated Electric Railway, will be inaugurated on Wednesday. At busy times in the day, a ten-minute service will be run, and the complete journey of nine miles between London Bridge and Victoria will take 24 minutes, including nine stops, as against 33 minutes as at present. At Victoria, seven lines have been equipped with the overhead gear, which supplies single-phase current to the trains at 6,700 volts. At London Bridge five platforms will be available. (Page 997.)

In his inaugural address to the Junior Institution of Engineers, Engineer Vice-Admiral H. J. Oram (Engineer-in-Chief to the Fleet) indicated some of the reasons why the various proposals for electrical propulsion of warships had not received the favourable consideration of the Admiralty. (Page 997.)

Mr. E. G. Tidd's inaugural address as Chairman of the Glasgow Local Section of the Institution of Electrical Engineers took the form of a review of the progress of electrical engineering during the last quarter of a century. He gave interesting historical particulars relating to telegraphy, telephony, electric supply, and traction, and the uses of electricity on board ship. (Page 998.)

In an article on the behaviour of direct-current machinery, special reference is made to the connections of the field windings of compounded and interpole machines. The adjustment of the current in the interpole windings and the position of the brushes of interpole motors and dynamos are dealt with, and the influence of brush position in the speed characteristics of interpole motors are referred to. By giving the brushes a slight forward lead, surging and the rise of speed on full load sometimes obtained with interpole motors are avoided. With reversible motors with the brushes in the neutral position, a series winding can be employed for the same purpose. (Page 999.)

In his presidential address before the new Illuminating Engineering Society, Prof. S. P. Thompson summarised the history of the science of illumination, and emphasised the urgent need for exact methods in natural and artificial lighting. In discriminating between the illumination at a surface and the specific brightness of the surface due to that illumination, Dr. Thompson called attention to the need for investigation into the reflecting properties of wall papers, &c., used in the decoration of rooms. The necessary degree of illumination for rooms and factories, the effects on the eye of non-uniform lighting, and the need for exact units were also mentioned. (Page 1001.)

THERE are persistent rumours of a coming amalgamation between the interests of the Western Union Telegraph Co. and the American Telephone & Telegraph Co., which, if true, may have considerable effect upon the Transatlantic telegraph business. (Page 1001.)

WE give particulars of a large number of schemes relating to electric supply and traction, which will be promoted in the Parliamentary Session of 1910. (Page 1002.)

IN his presidential address to the Newcastle-on-Tyne section of the Institution of Electrical Engineers on Monday, Prof. H. Stroud described the experimental wireless station of Armstrong College. (Page 1002.)

TERMS have been arranged between the City of London Corporation and the Smithfield Markets Electric Supply Co., under which a new concession is granted to the company until 1972, with the option of purchase by the Corporation in 1932 or 1952. (Page 1002.)

WE are able to publish, from an article which appeared in a German contemporary last Sunday, particulars of some highly successful long-distance telephone experiments. Conversation was carried on between Stockholm and Paris (by a route amounting to over 1,400 miles) with the aid of an Egner-Holmström microphone, in which a current of one ampere was employed. Other successful experiments were carried out on a circuit comprising 2,118 route miles, made up of 1,291 miles of copper wire 4·5 mm. diameter (502 lb. per mile), 823 miles of 3 mm. diameter (223 lb. per mile), and four miles of dry-core cable. (Page 1003.)

A PAPER read by Mr. L. E. Wilson before the Manchester Section of the Institution of Electrical Engineers contained a useful analysis of the faults occurring in private telephones. The remainder of the Paper touched upon various general points in connection with telephony, and the discussion also covered a wide range. In the course of the discussion, Mr. T. Plummer (G.P.O., Liverpool) gave some interesting results obtained by the Post Office in the course of experiments on loading trunk lines. (Page 1004.)

THE Local Government Board have refused to sanction a loan of £2,200 for street lighting in Finchley, for the reason that, in their opinion, the Council have not given proper consideration to the merits of gas.—The accounts of the Hanley Electricity Department for 1908–9 show a net profit of £416.—The dispute between the Llandudno Council and the local tramway company has been settled.—The London County Council propose to fit roof covers, by direct labour, to an additional ninety cars.—The Highways Committee of the L.C.C. have prepared a scheme for through running with the tramway systems of West Ham, East Ham, and Leyton.—The Stoke Newington Council refuse to make any contribution towards the cost of street widenings in connection with the reconstruction of the tramways from Finsbury Park to Southgate Road.—An explosion took place at the Southport Electricity Works last week which resulted in the death of an engine driver.—The Acton Council have had an application for a supply of 1,000,000 units per annum. (Page 1005.)

LEICESTER Corporation propose to spend £7,000 upon electrical extensions, and the Watford Council £7,500.—An expenditure of £4,500 upon cables is contemplated at West Ham. The Melbourne Council require A.-C. and D.-C. meters, and a feedwater oil eliminator. (Page 1006.)

MESSRS. MATHER & PLATT propose to distribute £200,000 from the reserve fund in the shape of fully-paid £1 shares as a bonus. (Page 1008.)

THE summonses under the Merchandise Marks Act against the Welsbach Incandescent Gas Light Co., Ltd., for applying a false trade description to their metal filament lamps were further heard at the Clerkenwell Police Court on Saturday. Evidence was given by Dr. Oberlander, technical adviser to the German Auer Co., and by Mr. Duncan Watson, to the effect that they were under the impression, from the advertisements, that the lamps were Osram lamps. From a statement made by one of the counsel, it appears that a patent action may also be expected. (Page 1009.)

A PAPER by Mr. W. T. Maccall read last week before the Leeds Local Section of the Institution of Electrical Engineers, described some experiments on the fusing currents of single and stranded fuses. (Page 1009.)

PROF. BROWN'S inaugural address at the opening meeting of the Dublin Local Section of the Institution of Electrical Engineers traced the historical development of the subject of magnetic testing of iron and steel, and gave a critical comparison of the various methods which have been proposed from time to time. (Page 1010.)

IN an address to the Students' Section of the Institution of Electrical Engineers, delivered on Wednesday of last week, Mr. J. H. Rider emphasised the importance of attention to detail in the design of electrical machinery and in the working of generating plant, and illustrated his remarks with interesting cases drawn from his own experience. Incidentally Mr. Rider touched on the subjects of the sub-letting of portions of contracts, and of acceptance of the lowest tender. (Page 1011.)

THE following books are reviewed in this issue:—"Berechnung und Konstruktion elektrischer Schaltapparate," by R. Edler; "A Text-Book of Sound," by E. Catchpool; "The Apprentice's Course of Experimental Physics and Mechanics for Preliminary Technical Students and Secondary-School Pupils," by J. L. Maxim; and "The 'Mechanical World' Pocket Diary and Year Book for 1910." (Page 1011.)

AN improved arrangement for giving an audible signal when the trolley standard on a tramcar accidentally becomes alive is described on page 1012.

AT the adjourned inquest on Thursday into the death of a guard who was found dead in a District Railway electric locomotive on November 9th, the jury returned a verdict of death from electric shock. We comment on the unsatisfactory nature of the evidence upon which this verdict was returned. (Page 1012.)

UNDER "Electrometallurgy and Electrochemistry" are given notes upon electrolytically prepared bleaching agents and on the properties of silundum, which is a carbide of silicon prepared in the electric furnace. (Page 1013.)

AMONG the specifications published by the Patent Office on Thursday was one by R. A. Fessenden for a method of high-speed wireless telegraphy with automatic transmission. W. P. Durtnall has one covering the "Paragon" and other systems of power transmission in which the frequency of the polyphase current supplied to the motor is raised in steps or gradually. Mechanism for reducing the power required to release the catches of circuit-breakers is described by M. B. Field and Ferranti, Ltd., and a construction for oil-immersed motor-controllers, in which the drum can be rotated about a horizontal axis to render inspection easy, is covered by R. F. Baerlocher. A specification by W. B. Thorpe relates to electrolytic meters. An improved form of ceiling rose, and a method of automatically regulating rolling-mill motors, are also described. Opposition has been entered to the grant of a patent for a method of fixing metal filaments to leading-in wires. The opposition to two patents relating to lamp-shade galleries and electric block signalling respectively has been unsuccessful. Leave has been granted for the amendment of H. S. Martin's patent for an adjustable carbon powder resistance. (Page 1014.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, NOVEMBER 25TH.

Institution of Electrical Engineers

8 p.m. At 25 Great George Street, London. "The Present Aspects of Electric Lighting," by H. W. Handcock and A. H. Dykes.

FRIDAY, NOVEMBER 26TH.

Physical Society.

5 p.m. At Imperial College of Science. Papers to be read include "The Effective Resistance and Inductance of a Helical Coil," by J. W. Nicholson.

Northampton Institute.

5.45 p.m. At Institute. "Single Phase Traction," by T. A. Collett.

TUESDAY, NOVEMBER 30TH.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. At University. "Recent Developments in High Tension Transmission on Overhead Lines," by Prof. E. W. Marchant and E. A. Watson.

Institution of Civil Engineers.

8 p.m At 25 Great George Street, London. Further discussion on the three Papers on Electric Traction, read on November 9th.

Faraday Society.

8 p.m. Annual General Meeting, at Institution of Electrical Engineers, 92 Victoria Street, London. Four papers are down for reading.

WEDNESDAY, DECEMBER 1ST.

Institution of Electrical Engineers: Glasgow Section.

7 p.m. Annual Dinner at the "Grosvenor," Gordon Street.

Institution of Electrical Engineers: Birmingham Section.

7.30 p.m. At University. "Research on Metallic Filament Lamps," by F. H. R. Lavender. "The Present Aspect of Electric Lighting," by H. W. Handcock and A. H. Dykes.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. At 92 Victoria Street, London. "Special Rheostats," by J. S. Messent.

THE SOUTH LONDON ELEVATED ELECTRIC RAILWAY

A REGULAR service of electric trains on the South London line of the London, Brighton and South Coast Railway between Victoria and London Bridge, which was the first line in this country to commence electrification on the single-phase system, will be inaugurated on Wednesday. In order to prevent any possible confusion with other electric railways, the line is to be known in future as the "South London Elevated Electric Railway." At busy times in the day a ten-minute service will be run, but at other times the interval will vary between twelve and twenty minutes. The time taken for the journey from London Bridge to Victoria (nine miles), stopping at each of the nine intermediate stations, will be twenty-four minutes, as compared with thirty-three minutes for the existing steam trains under similar conditions. Considerable reductions in fares, especially as regards season-ticket rates, will be made; only first- and third-class passengers will be carried, and a four-coach train will have seating accommodation for 238 passengers. A certain number of steam trains will be run at first in the early morning, and in consequence of the more frequent service numerous ordinary trains to and from London Bridge, Streatham, Tulse Hill, Sutton, Epsom, and Clapham Junction will be altered in time and accelerated by the withdrawal of stoppages at stations between London Bridge and Peckham Rye.

At Victoria Station seven lines giving access to five platforms have been equipped electrically, and at London Bridge five platforms are available. The equipment is on the single-phase system, with an overhead conductor supplying current to the trains at 6,700 volts, 25 cycles. The supply is taken from special generating plant in the Deptford station of the London Electric Supply Corporation. Each motor coach is equipped with four A.-E.-G. Winter-Eichberg 125-h.p. commutator motors supplied at a pressure of from 150 to 750 volts from transformers on the coach. To save time at the stations and to ensure the comfort of passengers, the coaches are constructed with side entrances, but a passage extends down the length of the coach, one half on one side, and the other half on the other side. The whole of the equipment has been carried out to the designs and under the direct supervision of Mr. Phillip Dawson, the electrical adviser to the Brighton Railway Co. Some further details of the rolling-stock and overhead equipment were given in ELECTRICAL ENGINEERING, February 11th, 1909, page 132, and April 1st, 1909, page 307, but we hope to give a complete illustrated description of the system shortly.

THE ADMIRALTY AND ELECTRICAL MARINE PROPULSION

IN the course of his inaugural address on "Propelling Machinery for Warships" to the Junior Institution of Engineers on Tuesday of last week, Engineer Vice-Admiral H. J. Oram (Engineer-in-Chief to the Fleet) made some reference to the question of electrical transmission gear with high-speed turbines and low-speed propellers for warship propulsion. His remarks were not particularly favourable to the innovation, but are of interest as indicating the way the matter is regarded in official circles. His remarks, of course, only applied to warships.

After recapitulating the claims made by advocates of the system that the greater economy of the high-speed turbines would outweigh the greater transmission losses, and that greatly improved economy at low speeds would be obtainable without increased weight of machinery, he pointed out that these were based on figures obtained from trials of electric light stations on shore, and it is somewhat doubtful if the same results will be obtainable when similar units are worked as a battery on board ship with the engines and boilers placed in from five to seven or even more separate water-tight compartments. The actual steam consumption in pounds per S.H.P. for the propelling turbines in the three ships of the "Indomitable" class is only 12 lbs. at full power, without superheating. The figure guaranteed for the steam consumption in one of the electrical schemes submitted was 12·9 lbs. per b.h.p. at the propeller shaft without superheat, and 10·9 lbs with 100° superheat, the vacuum being 28 in. In view of the fact that the loss of power in the dynamo and motor is some 12 per cent., there is in the case of the cruisers mentioned little margin of superiority at full power available for reduction of boiler power. He thought, however, that the claims of increased economy at low powers should be realised, and that the claim as regards increased power for going astern was justified. With regard to the allegations of inefficiency of high-speed propellers, he remarked that in the particular case of the large cruisers of the "Invincible" class there had been no falling off in propeller efficiency of the faster running screws from efficiencies obtained in the slow revolution screws of the older cruisers. Again, the diameter of the propellers was frequently limited by hull considerations, and electrically-driven ships, with the same number of propellers, driven slower, would in some cases be limited to practically the same dimensions as in direct-driven installations. In some of the electrical designs submitted the total increase in machinery weights was as much as from 15 to 20 per cent. The gain at low powers would require to be very substantial to balance such increases.

He considered that the voltages suggested were too high for safety in H.M. ships, and remarked that many details would require to be carefully considered, such as freedom from danger of failure due to access of water to the electrical machines, or to particular parts of them, and the ventilation of the machines. With the interposition of two electrical drives between the turbines and the propeller, it was not probable that the wear and tear would be less or that less staff would be required; but rather the reverse. In the designs submitted to the Admiralty there had been no gain in the space occupied, but in some cases an increase.

It was essential for warship purposes that the small variations of speed required from the propellers when keeping station in a fleet should be readily obtained, and in this respect the electrical systems which have been proposed to the Admiralty are far from satisfactory. The various firms had only proposed to provide for three electrical speeds, full, half, and quarter, and had suggested that if anything further were required that the speed of the generators should be regulated. This latter would detract from the economy of the system. He understood, however, that further attempts were being made to meet this condition.

Finally, he thought that the gain had not yet been demonstrated to be sufficient to outweigh the increased complication.

"We must recognise," he said, "however, the skill and ingenuity with which this problem has been dealt with, and any further developments will naturally receive careful consideration, especially the actual results from installations which are

Digitized by Google

about to be fitted on a small scale. The good work done by electrical engineers on board warships at present in respect to auxiliary machinery of all kinds is too well known to need any comment from me, and we should welcome their co-operation as regards the main engines if the resulting combination is likely to be beneficial."

THE PROGRESS OF ELECTRICAL ENGINEERING

At the inaugural meeting of the Glasgow Local Section of the Institution of Electrical Engineers, Mr. E. G. Tidd delivered his Presidential Address, which was devoted to a general review of the progress of electrical engineering since the foundation of the Institution. So far as Glasgow itself was concerned, the first lamp to be seen outside a laboratory was one shown at a restaurant in 1877, and the first permanent installation was put down at Queen Street station in 1880, although Mr. Mavor had carried out some temporary electric lighting at the Post Office in the previous year. Mr. Tidd then sketched out the career of the Institution from its foundation in 1871 as "The Society of Telegraph Engineers" to the present day, and referred to its impending move to a new home.

Passing on to engineering matters, he first reviewed the advances made in telegraphy, mentioning the first practical telegraph laid down in 1837, and the acquirement by the Government of some 30 land telegraph companies in 1870. Submarine work was, however, still chiefly in the hands of companies, of which there were now thirty-four, with a total capital of £36,283,038. The most prominent advance, however, was in the direction of wireless communication, first heard of in a practical form in Sir W. Preece's induction system, and now represented in the United Kingdom by some 152 stations, transmitting over 2,000,000 words per annum. He next came to the consideration of telephone enterprise, starting from the patents of 1876, and the amalgamation four years later of the Bell and Edison companies. The first telephone licence was granted by the British Post Office in 1881, and various companies which had sprung up were amalgamated into the National Telephone Co. in 1889. The trunk lines were purchased by the Post Office in 1896, and, as is well known, the whole undertaking will be taken over by the Post Office in 1911. Some figures relating to the growth of the National and Post Office services were given, and brief mention was made of the telephone position in Glasgow.

Turning to the subject of electric supply, he traced the first suggestion to the appointment of a Parliamentary Committee in 1879 to consider whether municipal corporations should be permitted to adopt electric lighting schemes. Enthusiasm was stimulated by the Paris and Crystal Palace Exhibitions of 1881 and 1882; in the latter year a Bill conferring and limiting the powers to undertakers for supplying electricity received the Royal Assent, and in 1883 no fewer than sixty-nine provisional orders were granted, but owing to the onerous conditions imposed by the Act sixty-two of these were subsequently revoked. Similarly the four orders granted in 1884 are all extinct. In 1888, however, a new impetus was given by the passing of an amended Bill, and between 1888 and 1896, 103 orders were granted to companies, and 157 to municipal authorities. Up to about thirty years ago, when the private Grosvenor Gallery plant started to supply some neighbouring premises in Bond Street, London, there had been no public supply. Other early pioneers were the Hove Electric Light Co. of 1882, and the undertakings at Hastings and Liverpool of the following year. Public supply in Glasgow dated from Messrs. Muir, Mavor & Coulson's station, started in Miller Street in 1887 for series arc lighting, and 110 volt incandescent lighting. The same firm also erected a 2,400 volt single-phase station in 1888 at 81 John Street, and the first Corporation station of 1,230 h.p. was opened at 75 Waterloo Street. Since that time the Port Dundas and Pollokshaw Road and Kelvinside station, now aggregating some 50,000 h.p., had been established, and at the present time 18,185 customers, 857 public arc lamps, 2,000 public stair lamps, and 4,292 motors, equivalent to 29,505 h.p., were being supplied. The existing stations were practically full, and he looked forward with interest to the next move.

Tramway progress in this country might be said to start from 1885 with the Besbrook and Newry line, but it was not till about 1896 that the country began to wake up to the possibilities of electric traction, and now £68,199,918 was invested in tramway schemes. The general tendency had been in the larger towns to work the tramways by municipal authorities, while suburban and country districts were mostly served by companies. In Glasgow the first route was experimentally equipped in 1898, but now there were 180 miles of track supplied by a plant of 13,000 h.p. Electric railways were only briefly treated. The City and South London and Liverpool overhead lines of 1890 and 1893 were mentioned as pioneers, and also the further development of 1904 and 1905 on the Lancashire and Yorkshire, North Eastern, and London Underground Railways. No reference, however, was made to the question of single-phase working. Electric motor cars driven by accumulators had not made great headway, but he saw possibilities in the use of electrical transmission gear for traction purposes on roads and railways, as well as on the sea.

During the period under review manufacturers had emerged from the shellac and sealing-wax period to a state of advanced standardisation, and great changes had been made in electric wiring methods and fittings, but he protested against the price cutting which was now hampering the electric wiring industry.

A branch of electrical engineering of particular interest in Glasgow was shipboard work, and he gave particulars of a number of installations, starting with that on board the Cunarder *Servia* in 1881, totalling about 13½ h.p., and leading up to extensive modern equipments of the *Lusitania* and *Mauretania*. The increase in the application of electricity in the Navy had been equally rapid. Twenty-five years ago dynamos were only just beginning to be introduced into the Navy, and then solely for lighting, but sixteen years ago electricity was firmly established as the illuminating agent, and first-class battleships were fitted with three dynamos of a collective output of 96 kw., the pressure being 80 volts, to suit the 24 in. searchlights, of which there were six. Besides supplying current to these searchlights, the use of electricity was almost entirely confined to ship lighting, there being about 700 incandescent lamps in use. In addition to these, cabin and voice pipe bells were operated and guns and torpedoes were fired by electricity generated by primary batteries. At the present day, the first-class battleships of H.M. Navy are being fitted with generators of a collective power of 600 kw.; the number of incandescent lamps has increased to about 2,000; the size of the searchlights has been doubled; and where beforetime there was no application of electrical energy to power purposes, there are motors of an aggregate horse-power of well over 1,000 h.p. Among the purposes to which it is applied may be mentioned ship and engine-room ventilation, coaling winches, boat hoists, capstans, pumping and refrigerating machinery, air compressors, ammunition hoists, passenger lifts, workshop machine tool driving, motor generators for the reduction of the pressure (220 volts) to suit the operation of the searchlights, and also of supplying low-pressure current for telephones (of which there is a large installation), voice pipe and cabin bells, gun and torpedo firing, and instruments for the transmission of orders to the guns. Electricity is further in use for such varied purposes as electric heating, cooking, X-ray apparatus, wireless telegraphy, telegraphs, stoking indicators, helm indicators, soldering irons, smithy forges, drilling machines, and numerous other tools. The Denny-Johnston torsionmeter, an electrical device, is also employed in the measurement of the power developed by the turbine machinery now universally employed for ship propulsion in H.M. Navy.

As an example of an early commercial application of electricity to welding, he mentioned an installation put down about eighteen years ago at Messrs. J. & E. Hall's works at Dartford, for butt welding of iron pipes for refrigerating machinery. Electricity had affected also every sphere of life, in the home, the workshop, and in ordinary business. Many commercial processes also owed their existence entirely to application of electricity. In 1896 the total capital invested in the industry was 61 millions, but he believed that it now reached the total of 386 millions.

A vote of thanks was proposed by Prof. Magnus MacLean (West of Scotland Technical College, Glasgow), who made several references to interesting features in connection with the past history of the local section, and the parts played in its formation by some of his *confrères*, who were now present with him to listen to Mr. Tidd's address. Only that day he had been reading a Presidential Address of another branch section, and it was interesting to note that it was only so recently as 1860 that the influence of the variation of magnetising force on the magnetic permeability of iron was generally known. It was not until 1870 that Rowland made a complete series of tests and published data bearing on the subject, and it was to them interesting to note that in 1882 a Paper was published by "Shida," a Japanese student at the Glasgow University, giving a *résumé* of the subject.

Artificial Illumination. In a lecture delivered at the London Institution on Monday, Mr. Leon Gaster dealt with the present state of artificial illumination, and touched on many interesting points, including the proposed standard specification for electric incandescent lamps, the need of more scientific methods in the arrangement of sources of artificial light for the protection of the eyes, and the importance of effective lighting in streets, schools, factories, and hospitals, &c.

Interruption to Supply at Woolwich.— A short-circuit on one of the street mains of the three-wire distributing system of the Woolwich Borough Council was the cause of an interruption to the supply for a little more than half an hour on Monday evening. The fault developed at 7.45 p.m., and though the particular section concerned was automatically disconnected, the resulting out-of-balance current caused the station balancer to be put out of order. In this way practically the whole system was affected, and the greater part of Woolwich was without light until 8.20 p.m., when everything was again in order. We understand that the actual cause of the fault has not yet been ascertained. The lighting of the streets was affected, many business premises were closed early, and the evening performance at the Hippodrome had to be abandoned.

SOME NOTES ON THE BEHAVIOUR OF D.C. MACHINES

(With Special Reference to Interpole Machines)

By P. Q. R.

Shunt Field Faults.—In the case of a generator which is required to be self-exciting there is only one correct connection of shunt field terminals to the armature bus-bars in order that the machine will build up. If the machine be run with correct rotation and does not build up, then probably the shunt field is wrongly connected, and should be reversed. Cases often occur, however, where the field is correctly connected (especially when the machine is being run up for the first time), and some half an hour will elapse before the machine commences to build up, or a machine may build up with the wrong polarity to be put on the station 'bus-bars. The remedy then is not in reversing the field connections (if this were done the machine would no longer build up), but in reversing the residual magnetism in the pole pieces by separately exciting the field from some external source for a short time. With a motor there cannot be an incorrect shunt field connection, because it is always excited direct from the line. The actual connection determines the direction of rotation.

Series Field of Compound-Wound Machines.—A generator running at constant speed will have its volts increased as load increases when the series field is correctly connected, and to obtain any degree of compounding it is usual to insert a low resistance or diverter in parallel with it, which can be adjusted for any value of voltage desired. In this way drop in engine speed can be compensated for between no load and full load

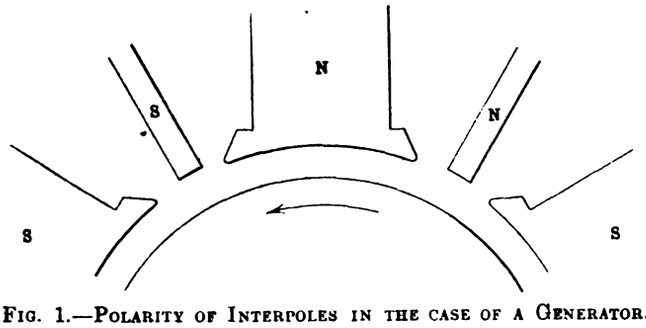

FIG. 1.—POLARITY OF INTERPOLES IN THE CASE OF A GENERATOR.

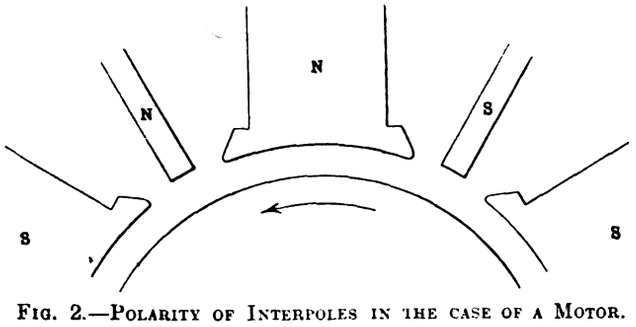

FIG. 2.—POLARITY OF INTERPOLES IN THE CASE OF A MOTOR.

as well as compounding, and there is no drawback to the use of a diverter, as is the case with interpoles. (See later.)

With a motor a diverter in the series field is rarely, if ever, used; the drop in speed due to the series turns can be foretold accurately enough, and there is always an allowance of 5 per cent. above or below rated speed with any direct-current machine. It is of the greatest importance, however, to be certain that the series field is right way when starting up for the first time, especially in a variable speed interpole machine. It would be safe in either case to run the machine light first of all. Load should then be put on very gradually, and if the speed tends to rise appreciably, it is almost certain the series field is reversed and bucks the shunt field; and in that case the machine should be at once shut down. The shunt field of a variable speed interpole machine is extremely weak when on top speed, and the series field, if reversed, is sufficient to wipe it out altogether, with the result that the machine would either race to destruction or arc over between the brush studs, thus blowing its own circuit-breaker and possibly shutting off the supply.

It is a common error also to suppose that the series field of a motor is wound to buck the shunt field, thus slightly weakening the shunt field on full load and keeping the speed constant at all loads. These differentially wound machines are rarely, if ever, to be found; the variation of 3 or 4 per cent. in speed between no load and full load of a good shunt motor is quite near enough a constant for all commercial purposes, and, moreover, it appears to be forgotten that any machine must necessarily be some 3 or 4 per cent. higher in speed when hot than when cold, due to increase of shunt field resistance and consequent weakening of field current.

Interpoles.—The object of commutating poles or interpoles is to neutralise the armature reaction at all loads, and thus leave the flux from the shunt poles undisturbed as much as possible; this will then allow of good commutation with a fixed brush position at all current values.

In practice the whole of the line current is carried round these poles, and the turns are sufficient to produce from 1 to 1·5 times the reactive ampere turns on the armature, according to the air gap. The exact proportioning of these parts is very important, for if badly designed the commutation might be even worse than if commutating poles had not been supplied. These poles have their winding always put directly in series with the armature of the machine, and after the connections have once been correctly made, they will be correct under whatever conditions the machine is to work, *whether motor or generator, or for either direction of rotation*, because for any reversal of current in the armature there will be a corresponding change of current and reversal of polarity in the interpoles. The correct connection is that which produces the polarity shown in Fig. 1 for a generator and Fig. 2 for a motor. The polarity is opposite in the two cases because the reversal of the armature current reverses the polarity of the interpoles.

Cases occur in which the ampere turns on the commutating

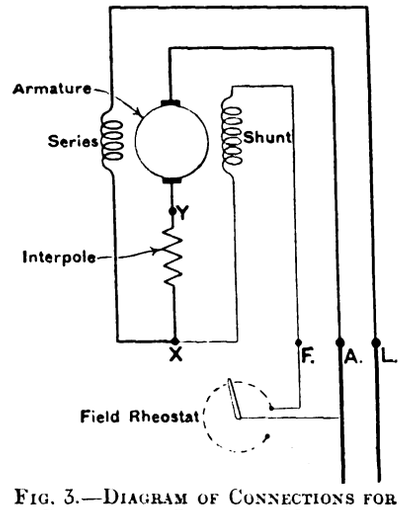

FIG. 3.—DIAGRAM OF CONNECTIONS FOR COMPOUNDED INTERPOLE MACHINE.

poles have too high a value; then, instead of rewinding new spools, the device of inserting a low-resistance in parallel with the interpole winding is resorted to, and by correctly adjusting this resistance the proper percentage of the total current is diverted through it, thus reducing the ampere turns on the interpoles to the correct value.

This, however, is not to be recommended, especially in cases where the load is fluctuating, because the turns on the interpoles, being wound on an iron core, possess a large amount of self-induction, which resists a rapid increase of current round the poles. When load then varies with a corresponding change in current, during the change the self-induction of the interpoles prevents a rapid change of current round them, and for the moment a greater percentage than normal passes through the low non-inductive resistance in parallel with them. The interpoles do not therefore at all times correctly compensate the current values of the armature, which results in sparking at the brushes. The difficulty could only be really overcome by winding the low-resistance mentioned above around an iron core, which would have approximately the same self-induction as the interpoles; the current would then be correctly proportioned between them for all changes in value.

Fig. 3 shows the usual connections of interpole machines. *X*, *F*, *A*, *L* represent the terminals on the connection board of the machine. *X* serves as a terminal for the equaliser bar, if one is required, in the case of a generator running in parallel

Digitized by Google

with others. *F* is the extremity of the shunt field, which is usually connected to the rheostat in the field circuit on the switchboard before being joined to the other side of the line. *A* and *L* are the armature and line main terminals coupled to the main switches. In the case of a motor the starting rheostat would be inserted between *A* and the main switch. The point *Y* is the connection of the interpole winding to one of the armature brushes; this is not brought out to the terminal board. If, therefore, the interpoles were of wrong polarity and required reversing (which would be easily detected on starting up the machine by the violent sparking when the brushes were in correct position), the connections could not be got at to do so, and the only way to overcome the difficulty would be to rock the brush gear one pole-pitch forward, thus reversing the armature relative to the interpoles.

In the case of a generator, this reversal of the armature would necessitate a reversal back again of the interpoles and armature *together* by interchanging *X* and *A* on the terminal board, thus bringing the armature as it was previously relative to the shunt and series fields to allow the machine to build up. With a motor this reversal of the armature would reverse the rotation; and to bring back the rotation to the original, interpoles and armature together are reversed by interchanging *X* and *A*.

Before considering the behaviour of these types of machines, it must be thoroughly understood at the commencement that brush position is the one all-important factor in successful operation. The commutating zone of a compole machine is very accurately defined, and the smallest alteration of brush position very greatly alters the characteristics of the machines.

The electrical neutral must in the first place be arrived at. Perhaps the best method is to find the brush position on which the machines will run at the same speed as a motor in both directions of rotation for the same applied voltage. Circumstances will not allow of this always, so the following mechanical method is more common and can be relied upon to have sufficient accuracy. By reference to Fig. 4 for a series-wound armature,

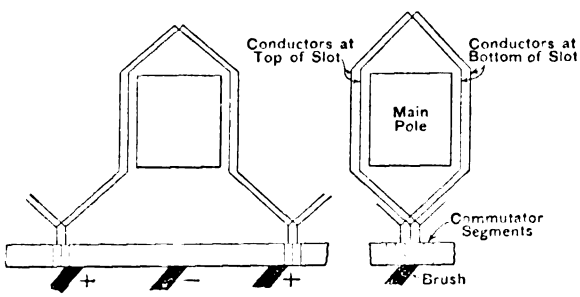

FIG. 4.—SERIES-WOUND ARMATURE. FIG. 4A.—PARALLEL-WOUND ARMATURE.

and 4A for a parallel-wound armature, the whole thing is made simple. Any armature coil is selected, and the armature is moved round until the slots in which the coil is wound are symmetrical with respect to the pole-tips of a shunt pole. The commutator segments to which the conductors in this coil are connected are traced out and the brushes are moved to lie symmetrically with respect to these. This brush position can be confidently assumed to be very near indeed to the electrical neutral.

The actual influence which interpoles have with different brush positions is very well illustrated in the following example: The machine under test was a 500-k.w. 500-volt 1,000-ampere generator, with interpoles but no series field. It was desired to run the machine on dead short-circuit with 1,000 amperes flowing. The only resistance then in circuit is that of the armature and interpoles, and it was found that with brushes on the electrical neutral the residual magnetism in the shunt poles was just sufficient to produce a voltage which caused 960 amperes to flow through the armature. When three segments' forward lead were given to the brushes, the 960 amperes above were reduced to 40 amperes.

Very often in practice, on the other hand, backward lead is purposely given to the brushes of an interpole generator when commutation will allow it, because then the interpoles are helping the shunt poles, and less shunt-field current is required for any given voltage. Again, with a motor, where commutation will allow it, quite an appreciable alteration in speed can be obtained by alteration in brush position; but interpoles are not supplied very often except with variable speed motors, the regulation of which is obtained by means of resistance in the shunt field. Brush position is then very important, since other difficulties arise on high speeds which definitely fix the position of the brush gear; but these will be considered later.

The difficulties in interpole generators are not very great. Sparkless commutation can be obtained with the brushes varying as much as two or three commutator segments; the only item which determines a fixed brush position is when the machine is required to have a certain degree of compounding. The distance of the brushes from the electrical neutral materially affects the amount of shunt-field current for a given voltage, hence it will be at once seen that there is only one brush position at which the compounding at all loads will be that desired.

With interpole motors the case is different. It might be that the motor is required to be reversible; this at once determines that the brushes must be on the electrical neutral. It might be that it must run at greatly different speeds, the extreme values of which could have a ratio of 5 : 1; or the speed on no load must be higher than full load, or *vice versâ*. For all these cases the interpoles require great accuracy in design to secure good results. The iron forming the pole-core should not be more than half saturated when full-load current is flowing, so that the flux produced is in direct proportion up to con-

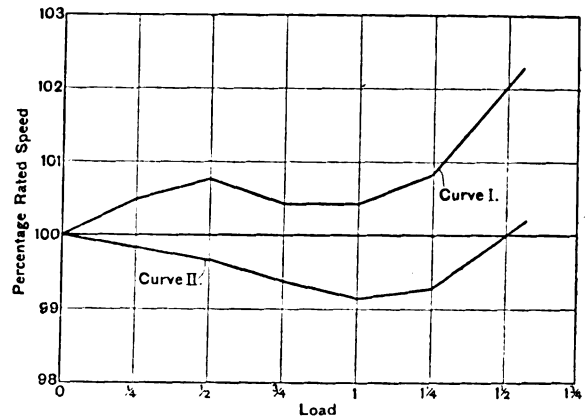

FIG. 5.—SPEED CHARACTERISTICS OF INTERPOLE MOTOR.
(I) BRUSHES IN NEUTRAL POSITION.
(II) BRUSHES GIVEN HALF A SEGMENT FORWARD LEAD.

siderable overload of the current, and thus fully neutralises the armature reactions at all loads.

If possible, an interpole motor is run with its brushes on the neutral, but in many cases when the machine has become hot there might be a slight tendency for it to surge on full load, or, if not on full load, perhaps on 50 per cent. overload. Besides this, the influence of the interpoles on the main field is such that the speed on full load and overload might be even higher than on no load.

Any tendency for the speed to rise on load should be remedied because on some overload or other the machine is almost sure to surge considerably, and in the event of a heavy overload for a short period at any time it will be damaged, due to the extremely heavy surging current values or to its racing to a dangerously high speed. The only remedy for this difficulty is to give the brushes, say, half a segment forward lead (but this, of course, cannot be done when the machine is reversible). The interpoles ought to allow of this and still give sparkless commutation if well designed. The additive action of the interpoles to the shunt field then keeps down the speed and at the same time keeps the field strong enough to prevent surging. Perhaps even in this case, if the speed at full load was lower than on no load, on 25 per cent. overload the speed might still be higher than on full load. The machine has not necessarily a drooping characteristic at all loads; hence it is worth while to ensure that the speed on 50 per cent. overload is going to be very little higher, if at all, than on no load. The speed characteristic of an interpole motor of 500 volts 40 h.p. 800 r.p.m. is shown in Fig. 5. Curve I. shows the speed with brushes on neutral position, curve II. with the brushes given half a segment forward lead. A good machine would usually allow of one segment forward lead being given to the brushes before sparking commences.

A much simpler way out of the above difficulty is to supply a series-winding, so that as load comes on the machine the series turns help the shunt field and keep down the speed and at the same time the machine perfectly stable. This is done in every case with a reversible motor, in which the brushes must necessarily be fixed on the neutral. In the latter case the shunt field and series field are in permanent connection to the supply line through the main switches, of course, and the interpoles and armature together are brought out to the reversing controller. With variable speed motors the value of the shunt field current on the highest speed is very small, and

Digitized by Google

in many cases in which a series-winding is employed as well, the machine would safely run on top speed without any shunt field at all.

When a series-winding is not employed the safety of the machine depends on this small value of shunt-field current.

The connecting cables from the various terminals of the machine are often threaded in any manner through the frame between the spools, when really this simple thing is a very important consideration. These cables carry the full-load current of the machine, and, lying as they do adjacent to a shunt spool, they are equivalent to half a turn practically round the spool. The influence of that number of ampere turns on the shunt spool when it is itself very weak is very considerable, and the result is that brushes collecting from conductors under its influence spark quite appreciably when all others are perfectly sparkless; there might be increase or decrease of shunt-field strength, but certainly there is bad commutation. Cables of this sort should always pass between the spools in pairs in which current passes in opposite directions.

In conclusion, a word might be said about the heating of such machines. In the first place the size for a given output has been reduced to a minimum and the space available is so well utilised that ventilation suffers considerably. It is safe to say that a machine whose output is limited by temperature will operate practically sparklessly at 25 per cent. overload, and take 50 per cent. overload for short periods without undue sparking. In many cases, too, the output can be considerably increased by the addition of a small fan on the armature shaft to aid ventilation, and by so doing the advantage of decrease in capital cost for a given output far outweighs any small loss in efficiency. In fact, cases often occur where, after the addition of a small fan, the efficiency is actually increased, due to the greatly reduced copper losses in the machine at the lower temperature.

EXACT METHODS IN ARTIFICIAL LIGHTING

THE inaugural meeting of the recently founded Illuminating Engineering Society was held on Thursday last at the Royal Society of Arts, London, when Prof. Silvanus P. Thompson, D.Sc., F.R.S., the first president, gave an address summarising the history of the science of illumination, and calling attention to the urgent need for exact methods in the regulation of natural and artificial lighting.

The Society, founded in May, 1909, has for its objects the impartial discussion of questions connected with illumination, both natural and artificial; the interchange of views among engineers, architects, and medical men; the furtherance of knowledge of the subject amongst the general public; and the development of illumination into an exact science. The list of vice-presidents includes such well-known names as Sir William Crookes, Sir William Preece, Sir James Crichton Browne, Prof. J. A. Fleming, Prof. Vivian Lewes, Prof. L. Weber, Dr. Louis Bell, Prof. A. Blondel, &c. The present members of the Council include Dr. J. H. Parsons, of University College; Mr. S. L. Pearce, of Manchester; Mr. Haydn Harrison; Mr. J. Eck, of the Union Electric Co.; Mr. L. Gaster (hon. secretary), Mr. F. W. Goodenough, Mr. R. J. Wallis-Jones, &c. The membership of the Society is already over 150.

After the report of the Council had been read, Prof. Thompson read his presidential address.

Prof. Thompson commenced his address by referring to the name "illuminating engineer," which, he said, had been appropriately given to one who dealt with the utilisation of light, intermediate between the producer and the user. Illumination was a new science, with only half a century of real development, and the general ignorance of the subject was "colossal." After sketching the history of the science from the discovery of the law of inverse squares, through Newton's work on Optics of 1704, and Lambert's assertion of the fundamental laws of photometry in 1760, to the recent invention of the illumination photometer, Prof. Thompson called attention to the urgent need for uniformity and precision in units both of light and of illumination. The recent preliminary agreement between the Standards Laboratories of some of the great nations had fixed the International Candle at a certain value equal to the French bougie decimale and 1·11 times the German Hefner. This was the ideal unit of light, and it did not matter whether it was realised by a Pentane, Hefner, or Carcel lamp. As yet, there was no similar agreement with regard to the unit of illumination, the British value of which was the candle-foot or the quantity of illumination on a surface one foot distant from a point source of light of one candle. The Continental equivalent was the candle-metre or Lux, but the latter term was used ambiguously, and should be avoided.

Turning to the question of the illumination of rooms, &c., Prof. Thompson said that reading was difficult and fatiguing with an illumination of ¼ candle-foot, comfortable with 1½ to 3 or 4 candle-foot, but fatiguing on account of the glare if a figure of 6 or 8 were exceeded. In general the illumination should never be less than 1 candle-foot. Size of print and eyesight had also to be considered. A pressing need was the establishment of exact rules to ensure the adequate lighting of schools, as insufficient lighting had been proved to be very detrimental to the eyesight. Illumination could now be expressed in definite significant figures, and should be specified in Government and other regulations, and in specifications for new buildings. In Holland only was there any attempt to give a definite figure to ensure the "adequate" lighting of factories; there the required value is 10 to 15 candle-metre, or rather more than 1 candle-foot. The application of scientific methods to the regulation of public street lighting had already commenced, as was exemplified by the reports of Mr. Voysey on the lighting of the City of London.

There were, continued Dr. Thompson, three kinds of photometers, measuring respectively: (1) the intrinsic brightness of sources of light in candles; (2) the illumination at a surface in candle-foot (which was independent of the nature or colour of the surface); and (3) the specific brightness of a surface in candle power per sq. in. or per sq. ft. This last class of measurement could be divided into two kinds—namely, the measurement of the brightness of a surface giving out light, such as the crater of an arc, and the brightness of a surface reflecting light. The brightness of a surface under a given illumination was dependent upon the nature and colour of the surface, and was a subject which needed much investigation. The choice of colour and texture of wall-paper, paint, and of decorative hangings was determined by this. Dr. Thompson then referred to the important work of Mr. A. P. Trotter in connection with illumination photometers, and to the photometer devised by Mr. Haydn Harrison. An important work for the Society, he said, would be the formation of technical committees to inquire into various matters. Among subjects needing investigation were the above-mentioned specific brightness of various surfaces under given illumination, the quantitative effects of diffuse refraction by ground-glass and other diffusing globes, the physiological effects on the eye of bright sources of light, and the best methods of artificial illumination from this point of view. It was not yet known whether the contraction or expansion of the iris was determined by the total amount of light entering the eye, or by the intensity of the image on any particular part of the retina. The influence of the degree of illumination of the surroundings when reading was another important question. His experience was that reading was most comfortable when the book was well lit, with the rest of the room somewhat in the shade. On the other hand, the contrast of a brightly-lit book in a dark room was bad for the eyes. The first paper to be read before the Society would deal with this subject, and was entitled "Glare and its Avoidance."

THE TELEGRAPH AMALGAMATION

PERSISTENT rumours are still afloat (and repeated again in the *Standard* of 17th inst.), notwithstanding the denials issued by the Mackay Trust, that large interests have been secured in the Western Union Telegraph Company by the American Telegraph and Telephone Co., an associate of the Mackay Companies. Taking into consideration the vastness of the American Telephone and Telegraph Company's capital and the comparatively small capital of the Western Union, as quoted in the *Standard*, it would appear quite within the bounds of possibility that an amalgamation of interests will come about, more particularly in view of the rumoured interest of the United States Government to acquire landlines and telegraph interests. They are owned by nearly all the Continental countries, and Canadian provinces have made some steps in this direction. Combination and Trusts are the rule of the day in the States, and in view of possible enforced purchase, a combined telegraph system would hold a firmer control than two rival concerns, for if the United States Government were able to acquire either interests, it would be readily able to force the remaining one to come to terms at a price. It is conceivable in view of the decision recently given in the case of the Standard Oil Trust, that it would not be desirable to spread knowledge of the companies' intentions, and if the Mackay Trust succeeded in gaining control of the whole of the landlines and telephones, the outlook for the British Atlantic Companies would not be so rosy, and it might even lead to these companies, already to a great extent permeated by American influence, being more Americanised than they are. The British Government should closely watch these happenings, and take all steps necessary to preserve to the country really British communications, and in every way create them where they are absent, and consolidate the whole of the British undertakings in a way to protect them from foreign aggression.

THE PARLIAMENTARY SESSION OF 1910

PARTICULARS are now available of some of the Bills which will be deposited in Parliament for the session of next year.

It is proposed to amalgamate the Baker Street & Waterloo Railway Co. and the Charing Cross, Euston & Hampstead Railway Co. with the Great Northern, Piccadilly & Brompton Railway Co., and to work them as one undertaking, the name of which, however, has not yet been decided upon. The construction of a loop line at Charing Cross to link up the Hampstead and Bakerloo lines is also proposed.

The Baker Street & Waterloo Railway Co. propose to deposit a Bill dealing with a number of minor matters, including an extension of the Oxford Circus Station premises, agreements with other companies as to joint stations, &c.

Bradford Corporation Bill includes the construction of tramways, running trolley 'buses and suplying electricity outside the borough boundaries.

The Board of Trade give notice of their intention to promote a Bill constituting the London County Council purchasing authority of the undertaking of the Kensington & Knightsbridge, Notting Hill, St. James's and Pall Mall, Westminster Electric Supply and Central Electric Supply Cos. These companies were not, owing to a technical reason, included in the London Electric Supply Act of 1908.

Nottingham and Huddersfield Corporations propose to construct additional tramways.

Lancashire Electric Power Co. will apply for a Provisional Order to sell electrical energy in Radcliffe in competition with the Corporation.

Leeds Corporation will ask for powers to install the trackless trolley system from Leeds to Farnley.

The scheme of capitalising the arrears of dividends on the 4 per cent. guaranteed stock, in addition to making a number of other financial rearrangements, forms the subject of a Bill by the Metropolitan District Railway Co.

Devonport & District Tramways Co. will seek to amend their Act of 1898, which, among other things, prescribes the annual payments to be made to the Corporation, fixes the time in which the company may be required to sell their undertaking to the local authority, &c. This Bill is the outcome of the recent proceedings between the company and the Corporation regarding the terms upon which the leased lines are to be operated.

An application will be made by the Cavehill & Whitewell Tramways Co. for running powers over the Belfast Corporation lines.

The Reading & District Electric Supply Co. will apply for an extension of area, &c.

The incorporation of the Havant Gas & Electric Co., consequent on the dissolution of the Havant Gas Co., is proposed.

London County Council's Bill proposes to construct a large number of tramways in different parts of London, particulars of which have already appeared in our columns.

Middlesbrough Corporation will apply for further powers with regard to their electricity undertaking, including the supply of meters, fittings, &c.

North-East London Railway Co. will apply for an extension of time for the acquisition of lands, and for the construction of the railway.

An extension of time for the construction of authorised tramways will be sought by the London United Tramways Co.

Doncaster Corporation will apply for powers to construct additional tramways under the Light Railways Act.

Metropolitan Railway Co. will ask for an extension of time for the completion of works authorised in 1902 and 1906, &c.

An extension of time for the completion of the extension of the Great Northern & City Railway from Lothbury to the Bank will be applied for.

An Electric Lighting Provisional Order will be applied for by G. H. Cox and H. J. Falk for supplying electricity in the Runcorn urban and rural districts, and also for Widnes. The Castner Kellner Alkali Co., Ltd., will also apply for an Order for Runcorn. Bath Corporation will seek to extend the electric lighting area at present defined by their Order of 1896. An extension of electric supply area is also proposed by the Derby Corporation. A new company is proposed for supplying electricity in Farnham. Alteration and amendment of the Ormskirk Electric Lighting Order, 1900, will be sought by the District Council. Church District Council will apply for electric lighting powers. Clevedon Council, the Brumby and Frodingham Council, the Chesham Electric Light & Power Co., and the Frimley Council will apply for electric lighting powers.

Extensions of tramways and powers to supply electrical fittings will be sought by the Southampton Corporation.

Sheffield Corporation propose to supply electricity in the parish of Tinsley.

An amendment of the Smethwick Electric Lighting Order, 1898, will be sought by the Birmingham & Midland Tramways, Ltd.

Hastings Corporation will apply for further powers in regard to their electricity undertaking, including the supply of fittings, &c.

North & South Shields Electric Railway Co. propose the revival and extension of powers for purchase of lands, and an extension of time for the completion of the railway.

Morecambe Tramways Co. will ask for powers to reconstruct their tramways for electric traction.

Salford Corporation will apply for powers to hire out electrical apparatus, &c.

Considerable extensions of the Rhondda Tramways will be sought.

ARMSTRONG COLLEGE WIRELESS STATION

IN his address to the Newcastle-on-Tyne Section of the Institution of Electrical Engineers at Armstrong College on Monday, Prof. H. Stroud, D.Sc., described the experimental wireless station of the College. The antenna comprises about 1,500 feet of seven-strand cable, made up of No. 20 S.W.G. silicium bronze wire. A double cable, about 170 feet long between the insulators, is stretched between two towers 130 and 80 feet high respectively. Two sets of cables suitably spaced along these two main wires, lead to the room where the signals are sent and received. By separately insulating the two sets, the antenna can be used as a "loop" antenna, or, by joining all the cables at their lower ends, as a "fan" antenna. The leads are brought into the room through two leading-in tubes of porcelain, to a switch which enables the antenna to be joined to the spark sender, the Poulsen arc sender, the earth, or the receiving side. The earthing wire, used for sending and receiving, is connected to a lead roof. The spark-sending circuit includes an 18-in. Apps' coil, excited from the A.-C. supply or from storage cells, a capacity of Leyden jars, an inductance of copper tubing, and various spark gaps. The capacity and inductance are adjusted for a wave length of 600 metres. The coupling with the antenna circuit is direct. Weak coupling is provided by making only one or two turns of the inductance common to the closed oscillation circuit and the antenna circuit. The Poulsen arc generator has a separately excited magnetic field. The arc is struck between copper and carbon electrodes inside a chamber with marble sides, with means for admitting hydrogen, coal gas, &c., and a spirit dropper. The arc is fed from the city D.-C. supply, air-cored choking coils preventing the oscillations from passing to the mains. One terminal of the arc is connected to earth through a capacity (block condenser), the other terminal being connected through a similar condenser to the main inductance and capacity. The latter is an oil condenser and both it and the inductance can be changed to give various wave lengths up to 1,500 metres. The sending key short-circuits either an extra capacity or an extra inductance in the antenna circuit, so as to produce variations in the wave length.

The receiving circuit comprises a primary coil of No. 14 wire on an ebonite cylinder (12 in. diameter). Spring contacts connect the turns in use to the antenna and to earth, a variable condenser being arranged in parallel. By means of a double-pole-change-over switch, the condenser can be instantly put in series between the coil and earth. In this way the wave length can be adjusted between wide limits from about 300 metres up to nearly 4,000 metres. Inductively coupled with this is the secondary coil, which slides within it, and is connected to the detector. Another secondary wound on an ebonite cylinder (13 in. diameter), with a finely stranded conductor consisting of 21 strands of No. 35 silk-covered wire, is used as the receiving circuit for the undamped Poulsen waves. Variable condensers are joined to the turns of this coil, and adjustment of the wave length is made by means of contacts on the secondary and the variable capacity. By means of a Poulsen "ticker" the energy, accumulated by resonance, intermittently charges a condenser across which is the receiving telephone. The coupling between the tuned primary and secondary of the Poulsen receiver is varied by the rotation of the secondary before one end of the primary coil.

Besides the above, the author described briefly the Telefunken system, in which advantage is taken of the large damping of a series of very short sparks. The primary oscillations are "quenched" by this damping after but one or two swings, and the secondary circuit continues to oscillate in a single period, giving rise to a wave of definite length. One of the principal advantages of this system, he said, was the musical tone produced in the telephone at the receiving end; this was distinctive of the station transmitting, and very different from the noise of atmospheric disturbances. In the Lepel system, he continued, one very short cooled spark between two flat metal plates, three inches in diameter, is used. These plates are separated by paper except at the centre, and the supply voltage is 400–500 volts. The receiver in this system contains two tuned circuits, the aerial and the intermediate, and an aperiodic circuit in which is a detector of the thermoelectric type. (See ELECTRICAL ENGINEERING, May 13th, 1909, p. 434.) Finally, Prof. Stroud briefly explained the principle of the Bellini and Tosi system of directive wireless telegraphy.

The address was interspersed by a number of experiments and the exhibition of forms of radiotelegraphic apparatus, including the Fleming cymometer, the tantalum, electrolytic and other detectors. In addition, some experiments were made to show by analogy the reaction occurring between the primary spark circuit and the secondary antenna circuit, and the effect

Digitized by Google

of quenching the primary oscillations upon the oscillatory impulses transmitted to the antenna, as made use of in the Telefunken system.

At the close of the lecture a demonstration, arranged by Prof. Stroud, in conjunction with Mr. Morris-Airey and Mr. Sorensen, was given in the radiotelegraphic room of the Physical Department. The Poulsen system was shown to be capable of use in conjunction with other systems which do not use persistent or undamped waves. This was accomplished by sending from the Cullercoats radiotelegraphic station undamped waves, the series being successively interrupted there by means of a revolving commutator. In this way they could be received by an ordinary spark receiver, and in the College telegraphic room a thermo-electric detector was arranged in circuit with telephones, by means of which the letters L. M. S. (the distinctive letters denoting the Cullercoats sending station) could be heard by the members of the Institution who attended the demonstration.

ELECTRIC SUPPLY IN SMITHFIELD MARKETS

AFTER a long period of uncertainty as to the future of the Smithfield Markets Electric Supply Co., arrangements have at last been made with the City Corporation, which once more puts the company upon a sound footing for a considerable period. It will be remembered that for some time past the directors have felt unable to recommend payments of any dividends pending the completion of a new contract with the City Corporation. This contract, which has now been entered into, gives the company a concession until 1972, subject to the Corporation receiving quarterly a rent equal to the following percentages on the gross receipts: 1 per cent. on the first £5,000 revenue; 2½ per cent. on the next £10.000, and 5 per cent. on all over £15,000. The rate for shop lighting must not exceed the average price charged in the City, plus an additional 1d. per unit for installation and maintenance. The present maximum of 4½d. per unit for lighting is to be maintained, and the present rate to lighting consumers who use carbon filament lamps must not be increased. It may be mentioned that the company supply and renew carbon filament lamps free of charge. The agreement leaves the company free, should it desire to be so, to increase the rate per unit to users of metal filament lamps. The company must supply current for power purposes at rates generally charged under similar conditions by other companies within the City of London, but the maximum rate must not exceed 1d. per unit.

As already mentioned, the new concession is until December, 1972, but the City Corporation have the right to purchase the company's undertaking in the years 1932 or 1952, and at either of these dates the purchase price will be on the basis of fair value, no consideration being had for goodwill. In all probability the price will be a matter of arrangement between the two parties.

The directors are not proposing to consider the installation of new plant as a consequence of the long term of years which the company has before it, as a supply in bulk is now being taken from the Charing Cross, West End, & City Electricity Supply Co., in conjunction with the supply from the company's own generating station.

It is the intention of the directors to at once arrange for the repayment of the second debentures and to form a sinking fund for the redemption of the £50,000 debenture stock.

LONG-DISTANCE TELEPHONY

MESSRS. CARL EGNER, the chief engineer of the Stockholm telephone administration, and J. C Holmström, the inventors of the new telephone transmitter with which such successful experiments in long-distance conversation have been carried out, have published an article in last Sunday's *Elektrotechnischer Anzeiger*, in which they describe some of these experiments.*

The authors state that the transmitter they used for the experiments took about 1 amp. in all cases, but that it can work with a considerably greater current if necessary. A special form of the instrument for wireless telephony worked continuously with a current of from 10 to 15 amperes without giving any trouble. Laboratory experiments showed that the energy of the oscillations generated by the Egner-Holmström microphone was many times greater than that generated by an ordinary modern telephone transmitter under similar conditions. Further, from experiments made with an artificial cable, it was found that whereas the limit of operation with the standard Swedish and German telephones was reached with 1,000 ohms resistance and 20 microfarads capacity, the new instrument gave fully satisfactory results with 1,500 ohms and 30 microfarads.

For one of the experiments on an actual overhead line, a loop approximately 2,000 route miles long was formed of some of the Swedish trunk lines, all 4·5 mm. (502 lbs. per mile) copper, with the exception of 42 miles of 3·0 mm. (223 lbs. per mile) line, and 5 miles of paper cable. The total damping coefficient for an average frequency of 800 per sec. was 6·05. Conversation was not possible with an ordinary telephone, but was quite satisfactory with the Egner-Holmström instrument. Another similarly successful trial was made on a loop of 2,118 route miles, comprising 1,291 miles of 4·5 mm. copper line, 823 miles of 3·5 mm. (304 lbs. per mile) line, and 4 miles of paper cable. This line had a damping coefficient of 8 for an average frequency of 800. Other experiments over 1,360 miles of 3·0 mm. copper wire, with a damping coefficient of 7·3, and over 200 miles of 3·0 mm. iron wire, and 12 miles cable, with a total coefficient of 6·3, also gave satisfactory results. Conversations of a thoroughly commercially satisfactory nature were carried on over lines with coefficients of from 6 to 7, whereas with the standard instruments the maximum value at which speech was possible was 3 to 4. It is noted in the article that the current has to be increased considerably for these long-distance conversations, at a far greater rate than in proportion to the damping coefficients.

Perhaps the most interesting experiments were those made over the international lines by arrangement with the Swedish, Danish, German, and French telephone administrations. The first of these, made on June 1st and 2nd, 1909, was between Stockholm and Berlin, and was most successful. The instruments were connected to ordinary subscribers' stations in this and all other experiments. The total length of the route was 800 miles, of which 360 miles was 5 mm. (619 lbs. per mile) copper wire in Germany, 414 miles was 4·5 mm. copper wire in Sweden, and the remaining 26 miles was submarine and underground cable. On June 5th and 6th, communication was established between Stockholm and Cologne, a distance of 940 miles. The line comprised 686 miles of 4·5 mm. copper wire, 225 miles of 4 mm. wire, and 29 miles of underground and submarine cable. In this case, the Egner-Holmström transmitter at Stockholm was shunted by a non-inductive resistance. This, it was found, could be reduced to 100 ohms without making hearing at the Cologne-end impossible, and with a shunt of 150 ohms, the words at Cologne were sufficiently distinct to carry on a commercially practical conversation.

Communication was established between Stockholm and Paris on June 11th by special arrangement with the various authorities. A 5 mm. copper line ran from Paris to Frankfort-on-Main, and from there *via* Hamburg and the German-Danish submarine cable to Denmark, and *via* Copenhagen, Elsinore, and Helsingborg, to Stockholm. In Denmark and Sweden, a 4·5 mm. copper line was used. The total length of the route was 1,410 miles, including nearly 30 miles of submarine and underground cable. The French Ambassador at Stockholm took part in these tests, and conversed with his wife in Paris. Afterwards, the line was extended from Stockholm to Sundsvall, a further 360 miles, and conversation was equally well maintained.

All the above experiments were carried out with a current of one ampere, which was found to be more than sufficient in all cases. No experiments were made with the shunt to the instrument on the Paris-Stockholm line on account of lack of time. In the case of the Berlin-Stockholm experiment, serious disturbance to neighbouring lines was caused, with consequent overhearing. These effects were more evident on the German lines, where the wires are merely crossed at infrequent intervals. On the Danish and Swedish lines, where the wires are rotated, the inductive troubles were not so evident.

Later experiments on the Swedish lines have shown that overhearing is not caused when the conductors are entirely faultless, but that the presence of leakage causes inductive effects. It is probable, the authors state, that the new instrument will be placed on the market with the adjustable shunt which enables the speaker to adjust the line current to the distance.

In conclusion, some particulars are given of the experiments with the form of the apparatus designed for wireless telephony. Experiments were made in conjunction with Mr. Valdemar Poulsen towards the end of June at the wireless stations at Lyngby and Esbjerg in Denmark. The Egner-Holström instrument was used at Lyngby, and successful transmission with a high-frequency current of six amperes was effected. The distance between the stations is 174 miles.

* A patent by these two gentlemen for a telephone transmitter which is in all probability the instrument in question, was published in October last, and an illustrated description of this transmitter appeared in ELECTRICAL ENGINEERING, Oct. 7th, page 877.

Electrical Equipment of Messrs. Galloways' Works.—It is stated that Messrs. Galloways, Ltd., of Manchester, have in hand the conversion of their works to electrical driving, mainly with the object of reducing the cost of production and providing additional facilities for the manufacture of Erhardt & Sehmer gas engines, which, as we recently announced, the firm have undertaken to manufacture.

SOME NOTES ON TELEPHONY

Suggestions for Improvements in Private Installations

MR. L. E. WILSON (of L. E. Wilson & Co., Manchester and Liverpool), read a short but interesting Paper on "Telephones" before the Manchester Section of the Institution of Electrical Engineers on Tuesday last week. Dealing first in a general manner with exchange working, the author referred to the enormous spread of telephony during the past twenty-one years. Twenty-one years ago, when Manchester was not connected telephonically with London, there were 1,400 subscribers there and about 5,000 subscribers in the Metropolis. A night service was inaugurated in London about this time, but with indifferent success, and from ten o'clock at night until six o'clock in the morning there were only forty calls per week, and it was estimated that each one cost 10s. Now at the present time some 18,600 calls are originated on the National Telephone Company's system in London nightly, between 8 p.m. and 8 a.m., and the 103,287 exchange stations as at January 1st this year originate 590,000 calls per day. In Manchester the number of exchange stations have increased to 20,000, giving 138,000 calls per day.

Mr. Wilson then referred to the tendency of business firms to crowd the day's work into about two hours in the morning and about two in the afternoon. This characteristic, he said, explains many engaged numbers, but engaged calls are chiefly caused by an insufficient number of lines. The "engaged number" provides ineffective work at the exchange on some 23 per cent. of the total number of calls. The Paper then alluded briefly to the "team work" arrangements in exchange operating, by which mutual assistance between the operators is relied on to prevent an accumulation of calls at individual operator's positions, and the work is apportioned on the basis of calls, not lines.

Engineering matters in connection with exchange work were only briefly touched upon. One of these, however, was the question of insulation. Taking 1,000 lines under old conditions, the author stated that on a wet day 40 per cent. tested under 100,000 ohms; the use of Sinclair-Aitken leading-in insulators, which introduces a dry section between the leading-in cable and the outside wire, raised the insulation considerably, and under the same atmospheric conditions only 23 per cent. proved to be under 200,000 ohms. An investigation of low insulation and the cause subdivided the responsibility, as follows:—Outside lines, including the leading-in wire, 37 per cent.; window terminals, 37 per cent.; office wiring, 19 per cent.; instruments, 7 per cent. After receiving individual attention, no line tested under 7 megohms.

Touching on the change from overhead wires to cable, Mr. Wilson recalled the fact that Manchester possessed one of the first paper cable systems, and it is interesting to note the increase in the number of wires per cable. In the first installation there were 153 pairs of 20 lb. wires in a 2½ in. cable, and now cables containing 800 pairs of 6½ lb. wires in the same diameter are used.

The latter half of the Paper dealt with private telephones, and we quote from this at greater length:—

The same excellence in the design and workmanship which is shown in exchange subscribers' telephones is not so generally noticeable in the domestic or private telephone; the retention of the obsolete types of instrument is unfortunate, old errors are perpetuated, and the consequent difficulty of maintenance brings the industry into disrepute. The practice of designing or specifying instruments equipped with 4-magnet generators and 1,000-ohm bell coils for internal use, where the maximum line resistance does not exceed 3 or 4 ohms, is absurd. In fact, for ringing currents, the resistance or impedance of the piece of apparatus operated should be something about the resistance or impedance of the operating apparatus plus the lines, but in the case of lines of negligible resistance one might very well use even a 50-ohm generator and corresponding bell. In some switchboards on the market the indicators are placed in series with the line, and series indicators, unless of very low impedance and used on short lines, are, of course, worse from a transmission standpoint than the bridging apparatus, and another point is that with series apparatus, by keeping down the impedance of the indicators, the sensitiveness is generally decreased, so that trouble is experienced owing to the fact that a more powerful source of signalling supply, whether battery or generator, is required. For some reason, also, most trembling bells are wound to 5 ohms resistance, and trouble is experienced when it is necessary to work the bells in conjunction with a cable line of, say, two or three miles with a resistance of, say, 250 ohms. This should obviously be wound so as to have the same resistance as the average type of line, and there appears to be no reason why the rule of thumb work should apply to the design of local service apparatus any more than it should to the design of long-distance apparatus.

The following analysis of faults, taken over a long period and a large number of instruments, given in relative order of importance, may be of interest:—

1. *Wiring.*—Much trouble can be traced to the practice of leaving at each terminal a spare length of wire in the form of a helix which is easily broken. The wire should be stapled direct to the terminals. Faults occur through placing cotton-covered wire in unsuitable positions or in steel conduit where moisture and condensation in time break down the insulation.

2. *Primary Batteries.*—The life of batteries varies according to circumstances, but they are often needlessly changed. The correct way to test is to leave the receiver off the hook for at least five minutes before making the necessary observations.

3. *Bell Troubles.*—After being adjusted correctly, the chief trouble is caused by cleaning gongs. Intermittent faults in the coils are often due to acids used in the manufacture of the bobbin fibre end, it is a difficult fault to localise even with a weak current. A generator current will oftentimes overcome the interruption to the circuit.

4. *Instrument Cords.*—The cords are the weakest parts of any system, and should be reduced to a minimum. For this reason the hand combination instrument is the most expensive to maintain. Its popularity is due to the convenience offered.

5. *Transmitters.*—Damage by pencils and the packing of granulated carbon is largely overcome by the use of the solid back microphone chamber with perforated mouthpiece.

6. *Generators.*—Short-circuiting of the generator due to breakdown of the insulating pin, caused by oil and metallic dust, occurs especially when the frame is used as a common connection.

7. *Receiver.*—A diaphragm too close to the magnet is a trouble which can be ascertained by the sound emitted when flicked with the finger; the sound should be hollow. Freedom from dirt is essential.

8. *Lightning Arrestor.*—This is generally of the serrated type, open and exposed to dust and foreign matter, which causes short circuits. Terminals left exposed to the atmosphere will, in a short time, cause trouble.

9. *Damp Walls.*—Fixing instruments to damp walls introduces various troubles.

10. *Cradle Switch.*—Such causes as poor springs and contacts, and the accumulation of dirt interfere with the regular working of some types of instrument switch-hooks.

For small installations it is not always advisable to instal a common battery equipment, but the time has now arrived when the advantages of a common battery system should be universally appreciated; but unless manufacturers take in hand the necessary educational work opportunities will, for the time being, be lost and obsolete systems installed. In a common battery system accumulators are usually employed, but there is no reason why suitable primary cells of low resistance should not be used for small plants.

Finally, the author weighed the relative advantages and disadvantages of the switchboard and intercommunication systems, and came to the conclusion that where a reasonable number of lines are available the switchboard system is undoubtedly the best. One of the troubles of the intercommunication system, he said, is due to the practice of adopting a single-line system to reduce expense. This produces overhearing and cross-talk, and he suggested that if manufacturers desire to retain this principle they might minimise the trouble by reducing the impressed potential on the line. With the ordinary 20 : 1 induction coil and 3 volts on the primary this is 60 volts, which he considered to be unnecessarily high.

DISCUSSION.

Mr. W. AITKEN (British Insulated & Helsby Cables, Ltd.) said that power and light engineers perhaps hardly realised to what an extent the telephone engineer was encroaching on their domains. For a large exchange the power plant might include a generator giving 1,000 amperes, accumulators having a capacity of 6,000 to 7,000 ampere-hours, and a power board perhaps as complicated as that of many power stations. The provision of fuses was very important, and the subdivisions were now very fine, *e.g.*, a fuse was now provided for each cord circuit. Referring to special insulators, Mr. Aitken mentioned that he had heard from an official in the telephone service that the special insulators now equalled in number the line insulators used; this was accounted for by the great amount of underground work, and by the underground distribution leading direct into the buildings in many cases. In his further remarks, the speaker said that he had no doubt that the completely automatic system would come. He condemned serrated lightning arresters, which he said might almost as well be painted on; carbon arresters should be adopted. He thought it a good arrangement to insulate instruments from the wall by mounting them on small insulators and pillars. Referring to small common battery equipments, he said that the practice of drawing current over the direct line, and feeding extensions from the same circuit by introducing capacity and self-induction, had been abandoned, because of the liability of the exchange line having an accident and cutting down the whole service. Current was now supplied over feeder wires. For small private installations there was, he said, no reason why a primary battery should not be used.

Digitized by Google

Mr. A. F. GUY (G.P.O., Manchester) said that when he came to Manchester, about fourteen years ago, to survey for the Post Office, the room for telephone work was something like 16 ft. square. Now it was probably 150 ft. long and 25 to 30 ft. broad, and had about 130 positions for operators; in fact, he believed it was the largest trunk exchange in the kingdom in one building. In the new post offices the general tendency was to build the telephone rooms and trunk exchanges considerably bigger than the telegraph instrument room.

Mr. L. R. MORSHEAD (Westinghouse Co.), speaking as a subscriber, asked whether it was not possible to devise some system whereby calls could be stored as put in, in a similar sort of way to the electric signalling arrangements on the underground railways. He also referred to the number of trunk calls that were ineffective to the subscriber owing to noise on the line.

Mr. T. PLUMMER (G.P.O., Liverpool) pointed out that Mr. Wilson's figures in connection with the National Telephone Co.'s calls worked out to about 10 calls per line per day in Manchester and about eight calls per day in London, both of which were higher than usual. He next referred to the small use made by subscribers of such facilities as telephoning express and ordinary letters, and the reduction in the price of trunk calls between 7 p.m. and 7 a.m. The "peak" between 10 a.m. and noon was also noticeable with trunk calls. At Manchester, which was the largest trunk exchange in the world, the trunk calls between 10 and 11 a.m. daily amounted to 10,000, of which 4,000 originated in Manchester. Between 11 and 12 this fell off to 8,000, of which the outgoing calls were 3,000. The great improvement in the manufacture of paper-core cables had been partly brought about by the agreement made in 1905 between the Post Office and the National Telephone Co., under which certain standards were laid down. This had enabled the company to reduce the weight of conductor in subscribers' cables within a short distance of the exchange to 6½ lbs. per mile, which represented the minimum size from a mechanical point of view, apart altogether from its electrical efficiency. Any man who was able to bring out a decent telephone cord would find a fortune awaiting him; there were cordless switchboards on the market, but they did not appear to have come into public favour. Referring to loading, Mr. Plummer said that the Liverpool-Manchester 100 lbs. conductor, air space, telephone cable had been under experimental treatment by the Post Office for some six years past. The cable was 38·5 miles in length, and the first sets of coils, inserted at mile intervals, although increasing the efficiency of the cable, gave rise to trouble through loss of insulation at the leading-in points. About two years ago, however, further experiments were made, and improved types of coils were fitted, one with an inductance of 100 millihenrys and the other 133 millihenrys, at three-mile intervals. The unloaded cable had had an efficiency represented by 17 miles of standard cable, whilst the loading at three-mile intervals had reduced this to about nine miles with terminal losses, or about five miles when the cable wires were extended so as to overcome these losses. The results had been so satisfactory that the new 208 wire telephone cable just laid between Liverpool and Manchester contained conductors of 70 lbs. per mile only, and these would be loaded at intervals of about 2½ miles. In conclusion, the speaker drew attention to the large number of small exchanges and public call offices opened by the Post Office, which, although resulting in a loss, helped to extend the general telephone system of the country. These were opened under guarantee; in the event of a deficiency on the cost of working, the P.O. bore two-thirds of the loss, and only asked the guarantors for one-third.

Mr. F. D. LATIMER (National Telephone Co.) corrected some of the author's statement respecting the various sizes of dry-core cable.

Mr. A. WHALLEY said that, up to five or six years ago, practically the whole of the equipment of the common battery exchanges was made abroad, but two or three firms in this country now, including the owners of foreign patents, had laid down plant, and everything was now made in this country. The Post Office was to be credited with a large share of this encouragement of British industry. The number of employees engaged in this country in making telephone exchange equipment and instruments was between 3,000 and 4,000, and, to keep them properly occupied, orders should average about £10,000 per week, or at the rate of £500,000 per year. He was afraid that not much more than one-third or one-quarter of that amount might be ordered next year, according to present signs. While in America they had an output of telephonic apparatus many times greater than ours, no universally accepted standards had so far been adopted. We had standardised here, and British telephone manufacturing firms could now work to definite standards of speaking efficiency, quality, &c.

Mr. A. R. BENNETT sent a communication containing some interesting historical notes, particularly with regard to all-night service.

After a few observations by the Chairman (Mr. S. J. Watson),

Mr. L. E. WILSON replied briefly to the discussion. In the course of his remarks he said that intercommunication telephones were not a complete success for systems of over ten lines.

LOCAL NOTES

ACTON: *Electric Supply.*—Messrs. D. Napier & Son, Ltd., have asked for a quotation which will enable them to close their generating plant and take all their supply from the Council, if they guarantee to take 1,000,000 units per annum. The Clerk has been instructed to communicate with the Metropolitan Electric Supply Co., Ltd., on the matter.

AUSTRALIA: *Telegraph and Telephone Losses.*—Evidence has been given before the Australian Postal Commission to the effect that last year's loss upon the telegraph service amounted to £71,000, and upon the telephone service £23,300.

BIRKDALE: *Street Lighting.*—The installation of electric street lighting is being proceeded with in Birkdale, and when the improvements are completed, there will be 3½ miles of street lighted by electricity.

DUNDEE: *Electric Lighting.*—A sub-committee has been appointed to deal with the scheme put forward by the electrical engineer, Mr. H. Richardson, for electrically lighting common stairs.

EPSOM: *Street Lighting.*—The Council have rejected an offer from the Epsom & Ewell Gas Co. to light the streets.

FINCHLEY: *Loan for Street Lighting Refused.*—At the last meeting of the Council the following letter was read from the assistant secretary of the Local Government Board, in relation to the recent application by the Council for a loan for street electric lighting:—"I am directed by the Local Government Board to advert to your letter of the 14th ultimo, with reference to the application of the Urban District Council of Finchley for sanction to borrow £2,200 for the provision of electric light arc lamps in Ballard's Lane, Regent's Park Road, and the Great North Road, Finchley. I am to explain that the Board's view is that before sanctioning a loan in this case they ought to satisfy themselves that the precise object for which the loan is to be sanctioned is one which would be in harmony with the interests of the ratepayers throughout the currency of the loan. In considering this question the Board must necessarily have regard to the relative advantages of other alternatives available, and it was for the purpose of that consideration that they have requested further information from the District Council. The required information has not been forthcoming, and in the circumstances the Board's decision can only be that in the absence of it they do not feel justified in sanctioning the proposed loan."

FLEETWOOD: *Appointment of Electrical Engineer.*—At the last meeting of the Council objection was taken to the Electricity Committee having issued an advertisement inviting applications for the post of electrical engineer to the Council without the proposal having been confirmed by the Council. It was explained that the Electricity Committee acted in this way in the interest of time, as they anticipated that whoever was appointed would have to give three months' notice to leave his present appointment.

GRIMSBY: *Electric Tramways.*—The Great Central Railway Co. are pushing forward with the work of constructing a light electric railway between Grimsby and their new docks at Immingham.

HANLEY: *Electricity Accounts.*—The accounts of the electricity department for the year to March 31st, 1909, show a total revenue of £17,092, and an expenditure of £9,575. After meeting capital charges, there is a net profit of £416. The number of units sold was 1,613,568, and the total maximum supply demanded was 1,102 kw. The works costs were 0·88d. per unit, and the total costs, including capital charges, were 2·40d. per unit.

KEIGHLEY: *Electricity Extensions.*—At the last meeting of the Corporation, reference was made to the proposal reported in our last issue to apply to the Local Government Board for a loan of £21,000 for extensions. After some discussion, it was decided not to accept tenders for the plant until the sanction of the Local Government Board had been obtained.

LLANDUDNO: *Supply for Tramways.*—As hinted in our last issue an amicable arrangement has been come to by the Council and the Llandudno & District Electric Tramway Co. with regard to the interpretation of the clause in their agreement relating to the supply of electricity. The agreement provides for a sliding scale, but the omission of the words "per annum" in certain cases led the company to argue that once the minimum consumption was passed, the lower rates would have to be charged in the following years, without the minimum supply having to be taken. The company, however, have assented to the Council's construction of the agreement, but this construction will not be acted upon until after the date of putting the settlement into writing. The Council have agreed to take a poll of the ratepayers, on the question of Sunday running at the expense of the company, the latter to give a month's notice of their desire for the poll to be taken.

Digitized by Google

LONDON: *London County Council: Roof Covers for Electric Cars.*—The Highways Committee report that the work of constructing 50 car-bodies with roof covers has almost been completed by direct labour at the Leytonstone car works. They now recommend that a further 90 double-deck cars should be fitted with top covers in the same manner.

Through Running in East London.—The Highways Committee of the Council have reported with regard to the proposed arrangements for the through running of cars from the Council's lines at Aldgate and Bow upon certain lines of the West Ham and East Ham Corporations and the Leyton District Council. In submitting the proposals, the committee point out that regard has been taken to the special circumstances of the routes affected, and they do not wish this agreement to be taken in any sense as a precedent to govern other cases which may arise in the future. In the present case it is proposed that each authority shall (1) take all fares on its own cars, (2) pay its own working expenses for operating cars, (3) supply electrical energy in its own area to the other authorities, and (4) run cars according to the length of track in its own area.

Tramways.—The Highways Committee recommend that car ploughs be fitted by direct labour to 200 new cars, and four electric car traverses.

Islington: Tramways.—The Borough Council have vetoed the tramway proposed by the London County Council from Seven Sisters Road to Hanley Road, on the ground that there is no public demand for it, and that if constructed, it would prejudicially affect the districts concerned.

Stoke Newington: Tramways.—The Borough Council have informed the London County Council that they are unable to agree to make a contribution of £4,460 towards the cost of street widenings in connection with the reconstruction of the existing tramways from Southgate Road to Finsbury Park. The Council, however, have no objection to the construction of the tramways.

MEXICO: *Electric Supply.*—The Puebla Tramway, Light, & Power Co. have presented a formal petition to the Government for leave to extend the company's electric power transmission lines into Mexico City and the Federal District.

NEWCASTLE: *Tramways Employees' Grievances.*—At a special meeting of the Newcastle Tramways Sub-Committee on Wednesday last week, a deputation was received from the Amalgamated Association of Tramway and Vehicle Workers. The grievances of the tramway employees were gone through seriatim, and where possible promises were made that they should be inquired into. One complaint referred to the further protection of motor men whilst driving. It was pointed out to the deputation, however, that even if the committee desired to change the present type of cars, they were unsuitable for alteration into vestibule cars. Moreover, the committee had no intention of building any new cars for some time, and expert opinion was against vestibule cars, mainly on account of the ill-effects of the glass on drivers' eyes.

NORTH BERWICK: *Electric Lighting.*—The Council have agreed to interview a representative of Messrs. Crompton & Co. relative to an application to Parliament for an Electric Lighting Provisional Order.

SOUTHEND-ON-SEA: *Tramways.*—The final section of the Corporation tramways was opened for traffic last week.

SOUTHPORT: *Explosion at Electricity Works.*—An inquest was opened at Southport last week concerning the death of W. Sanders, an engine driver in the electricity department of the Corporation. The deceased was in charge of engine No. 5 on November 12th, when an explosion took place which set fire to his clothing, and he succumbed to his injuries on the following morning. It appears that a statement was made by the deceased to the effect that in repairing the cylinder of the engine a short time previously asbestos packing had been put in instead of copper packing, and that the engine generally was very much out of repair. He also stated that an inferior oil which was being used was the cause of the explosion. The inquest has been adjourned in the hope that a fellow-worker, who was injured at the same time, will recover.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA.—According to *Commercial Intelligence*, the Australian Defence Department will shortly be inviting tenders for several electric light stations.

It is understood that an electricity works is to be erected at Mount Buffalo.

IRELAND.—The Ballyclare Council have decided to apply for sanction to borrow £3,000 for an electric lighting scheme.

LEICESTER.—A Local Government Board inquiry was held last week into an application for a loan of £7,000 for electric lighting purposes. The proposal is that the Tramway Committee shall extend their power station for the supply of direct current for power purposes.

LONDON: *Fulham.*—£300 is to be spent in extensions to afford a supply for power to the British Improved Construction Co.'s premises in Stevenage Road.

WATFORD.—At the last meeting of the Council it was decided to make application to the Local Government Board for a loan of £7,500 for mains, services, &c., within the next three years.

WEST HAM.—An expenditure of £5,400 is contemplated upon cables.

Miscellaneous

ARGENTINE.—The Buenos Aires Great Western Railway Co. have been authorised to extend its lines from Sadi Carnot Street to the lines of the Port of the Capital, passing under the City by means of a tunnel. Electric traction is to be employed.

AUSTRALIA.—Tenders are invited by the Melbourne Council by December 6th for 250 A.-C. and 160 D.-C. meters. Particulars from Messrs. McIlwraith, McEacharn & Co. Ppty., Ltd., Billiter Square Buildings, London, E.C. Tenders are also invited for the supply and delivery of a feed water oil illuminator.

LONDON: *London County Council.*—The Highways Committee recommend an expenditure of £6,400 on the construction of electric tramways in Farringdon Road. This sum relates only to the track work.

Port of London Authority.—The Port of London Authority have decided to provide electrically-driven pumping plant for the purpose of raising the level of the water in the Royal Victoria and Albert Docks by 2 ft. 6 in., giving the Victoria Dock a minimum depth of 28 ft., the Albert Dock 29 ft. 6 in., and Albert Dock Basin, 34 ft. 6 in.

NETHERLANDS.—The *Board of Trade Journal* states that the "Nederlandsche Spaar en Incassobank" of Amsterdam have applied to the Communal Council of Beverwyk for a concession for the establishment of an electric tramway from Amsterdam to Beverwyk and to Wyk an Zee en Duin.

OLDHAM.—The Lighting Committee are to take into consideration the lighting of Union Street with arc lamps.

TASMANIA.—Tenders are invited by December 20th for the supply and delivery of telephone material at Hobart, Tasmania. It will be noticed that, owing to the limited time available, this information is only of use to firms having agents on the spot, whom they can instruct by cable.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

London County Council.—The Asylum's Committee recommend an expenditure of £270 upon electric lighting at the Epileptic Colony.

S.E.—Three hotels in connection with the L.C.C. Residential Day Training College, Avery Hill, Woolwich (£26,255). Builders, F. and F. Thorne, Isle of Dogs.

PROVINCES.

BARNSLEY.—School. Builders, Union & Co., Ecclesfield, Sheffield.

BARRY.—Wesleyan Chapel (£4,393). Architect, H. Budgen, 95 St. Mary Street, Cardiff.

COLCHESTER.—Technical institute (£11,120). Architect, H. A. Cheers, Twickenham. Builders, F. Parkington & Son, Ipswich.

DARTFORD.—Additional workroom at Asylum (£3,750). Architects, T. W. Aldwinckle & Son, 20 Denman Street, S.E.

DOVER.—Rink. Architect, H. Dan, Faversham.

FOLKESTONE.—Rink. Architect, H. Dan, Faversham.

GLASGOW.—Rink. Architect, W. W. Morton, Rutherglen.

LEATHERHEAD.—School. Architects, Jarvis & Richards, 10 Queen Anne's Gate, S.W.

MANCHESTER.—Moss Side Mills, for Fry, Binns & Co., Manchester.

MIDDLESEX.—Sanatorium (£3,000). Colonel Gerard Clark, 4 Sussex Gardens, Hyde Park, W.

PRESTON.—School, Moor Park Avenue. Architects, Woodfall & Eccles, Bank Buildings, 60 Castle Street, Liverpool.

TAUNTON.—Domestic centre. Architect, C. Reilly, County Offices, Aylesbury.

WATFORD (Herts.).—Adaptation of 107 St. Alban's Road into bank for London County and Westminster Bank.

WOLSTANTON.—Residence (£960). Architect, R. T. Longden, Market Place, Burslem. Builder, J. Cooke, Wolstanton.

WORCESTER.—Banking premises. Manager, London City & Midland Bank, 3 Threadneedle Street, E.C.

WORKSOP.—100 villas, Garden City. Secretary, Worksop Co-operative Society.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

ALTRINCHAM.—The tender of Messrs. J. Swainson & Co., of Manchester, has been accepted at £249 for the electric wiring of the County High School for Girls.

DONCASTER.—The tender of the United Electric Car Co., Ltd., has been accepted for the supply of four top tramcar covers at £91 each.

LONDON: *London County Council.*—The Stores Committee recommend the acceptance of tenders of Messrs. Falk, Stadelmann & Co., Ltd., and the General Electric Co., Ltd., for lamp glasses, globes, and shades, the estimated value of the goods to be supplied being £826 and £28 respectively.

The tender of Messrs. Dick, Kerr & Co., Ltd., at £29,705 is recommended for acceptance for the reconstruction of Deptford Creek Bridge, including the laying of ducts for tramway and other cables across the bed of the creek, and the construction of manholes.

The Switchgear Co., Ltd., whose tender for high- and low-tension switchgear was recently accepted at £3,517, has withdrawn it. It is explained that the error was made by the firm whose machinery it was proposed to use for a portion of the work, and that when the consequential alteration was made the tender, instead of being the lowest, became higher than that of two other firms. The committee accept this explanation as satisfactory, and have now accepted the tender of Messrs. Johnson & Phillips, Ltd., at £3,625.

Metropolitan Asylums Board.—Orders have been placed as follows:—Evershed & Vignoles, new electric testing set for head office, £30 12s.; W. J. Fryer & Co., alterations to electric lights, South-Eastern Ambulance Station, £22 15s.; United Electric Car Co., additional fittings and appliances for ambulance tramcars, small-pox hospitals, £42 16s.

Westminster.—The General Purposes Committee recommend the renewal of the contract for three years with the Westminster Electric Supply Corporation, Ltd., for the supply of energy to the Council's premises at 2½d. per unit for lighting, and 1d. per unit for other purposes.

LUTON.—Messrs. C. Macintosh and Co. have received an order from the Council for single-core insulated cables.

SHANGHAI.—Messrs. Cryselco, Ltd., of Kempston Works, Bedford, have received the contract for the supply of "Cryselco" lamps to the Council for the ensuing twelve months.

WATFORD.—The Council have accepted the tender of Siemens Bros., Ltd., for the annual supply of electricity meters.

WORKSOP.—Mr. Haydn Harrison has received an order from the Council for 200 Osram lamps for street lighting at 3s. 1d. per lamp.

YSTRADGYNLAIS.—An offer by Messrs. Mills, English & Co., of Swansea, for the erection of an electricity works, and to provide street electric lighting at £2 10s. per lamp per annum has been accepted.

During the past month the following tenders have been accepted by the Government Departments named:—Admiralty—Incandescent lamps, Edison & Swan Co., Ltd., General Electric Co., Ltd.; lamp fittings, McGooch & Co., Ltd.; General Post Office—Cable, W. T. Henley's Telegraph Works Co., Ltd., British Insulated and Helsby Cables, Ltd., Johnson & Phillips, Ltd., Western Electric Co.; dry cells, Siemens Bros. & Co., Ltd.; unmounted generators, International Electric Co.; battery equipment and main switchboard installation at the Head Post Office, Bristol, Westminster Engineering Co., Ltd.; telephone trunk service equipment installation at the Post Office trunk exchanges, Sheffield and Bristol, British Insulated and Helsby Cables, Ltd.

Prosecution of Mine Managers.—The prosecution of the manager of the Fife Coal Co., Mr. C. A. Carlow; the manager and agent, Mr. H. Rowen, and the manager of the Fulford Pit of the Company was commenced at the Dunfermline Sheriff's court last week. The charge is that the persons named allowed defective electrical apparatus to exist in the mines, in contravention of the special rules relating to electricity in mines. Evidence was given against the defendants by Mr. J. Masterton, Assistant Inspector of Mines for the district, and Mr. Robert Nelson, H.M. Electrical Inspector of Mines, and the case was adjourned until December 6th. A full report will appear in our Mining Supplement next week.

Overhead v. Underground Telephone Wires.—At the West London Police Court last week, Mr. E. W. Garrett, one of the magistrates, sat again as arbitrator in a dispute between the Postmaster-General and the Hammersmith Borough Council with regard to the erection of overhead wires for certain telephone extensions. In our issue for Nov. 11th we reported the case for the Hammersmith Borough Council, which was to the effect that, for æsthetic reasons, underground wires should be installed. On behalf of the Postmaster-General, the question of cheapness of service was kept to the front, and the magistrate, in giving his decision, said he did not think the objections raised against the Postmaster-General's policy in this matter were sufficiently strong to warrant a decision in favour of the Hammersmith Council. He decided that overhead wires should be erected.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £61 5s. to £61 10s. per ton (last week £60 10s. to £61 10s.).

BANKRUPTCIES, LIQUIDATIONS, WINDINGS-UP, &c.—The trustee has been released in the bankruptcy of W. T. Garnett, trading as W. T. Garnett's Cable Co., Barkerend Mills, Bradford.

A meeting of the Victor Arc Lamp Co., Ltd., will be held at 8 Arthur Street West, London, on December 13th, at 3 p.m., for the purpose of hearing the liquidator's account of the winding-up.

AGENCY WANTED.—The *Board of Trade Journal* states that a Montreal correspondent is anxious to obtain the agency of a British manufacturer of electrical apparatus and supplies. Further information may be had from the High Commissioner for Canada, 17 Victoria Street, London, S.W.

CHANGE OF ADDRESS.—Messrs. W. P. Thompson & Co., Chartered Patent Agents, have removed their London offices to 285 High Holborn, London.

WORKS EXTENSION.—Mr. S. N. Brayshaw, of 2 Mulberry Street, Hulme, Manchester, informs us that he has had to make considerable additions to his factories, in order to cope with the increasing orders for his hardening furnaces and milling cutters.

APPOINTMENTS AND PERSONAL NOTES

The following increases of salary are proposed at West Ham: Mr. Lloyd Jones, station superintendent, £300 to £350, and by annual increments of £25 to £400; Mr. E. Seddon, assistant station superintendent, £3 per week to £190 per annum, and by annual increments of £10 to £210; Mr. W. A. Gilbert, mains engineer, £200 to £250, rising to £300 on April 1st, 1910; Mr. W. Whitney, assistant mains engineer, £150, to £175.

Mr. W. O'Brien, of the Formby electric power station of the Lancashire & Yorkshire Railway Co., has been appointed assistant mechanical engineer at the company's Locomotive Department, Horwich.

Telegraph Traffic and Movements of Cable Ships.—The state of the West Indian cables and telegraph lines is nearly as bad as it was last week, and, to make matters worse, the cable of the West India & Panama Telegraph Co. between Jamaica and Colon broke down on the 8th inst. The Jamaica land lines have been restored, however, re-establishing communication with Kingston. The c.s. *Henry Holmes*, in dock at Trinidad repairing boilers at the time of the hurricane, hastened to the scene to repair the Jamaica-Puerto Rico cables, but she has not yet succeeded in putting them through. The Jamaica-Ponce section broke on the 8th, and the Jamaica-St. Juan section on the 10th inst. In the meantime telegrams are being sent by mail from the nearest island or port, and opportunities have been announced from New York, Santiago de Cuba, and Bermuda. So far as is known, the cables beyond Puerto Rico are all working, and when messages are sent by rail to any one island, they are forwarded by cable to destination, the rates collected being the same.—The French Cable Co.'s lines between Puerto Plata-Martinique and Cape Haiti-Mole St. Nicolas, as well as the sections between Dutch Guiana and Brazil, have not yet been repaired, but the cable steamer *Relay* is expected to arrive at Jamaica (Kingston) about the 24th inst., and a quick repair is expected.—The Commercial Cable Co. have the Havre-Waterville section in the hands of the *Buccaneer*, she being actually at Havre, and the work in hand will soon be completed. The fault being cut out is due, it is believed, to the magnetic storm experienced in September last.—Telegraphic communication by the normal routes with the towns of Mevado, Hwandung, and Gorontalo in Celebes, and with the Caroline Islands, is interrupted. These places may, however, be reached *via* the Atlantic cables and the Commercial-Pacific system. The route of the Indo-European Telegraph Co. is cut between Emden and Berlin, no doubt due to the very heavy weather recently experienced near the German capital.—The El Arich and Hanekine routes were restored on the 18th inst., while the former was again interrupted between Adana and Beyreuth on the 20th inst.—On the 21st inst. delay was ruling on Russian telegrams owing to snowstorms and bad weather, and telegrams have to be sent at present by circuitous routes until restorations have been effected.—According to the *Times*, the Western Telegraph Co.'s Direct Cable Bill has been passed, in spite of efforts made by the German Minister to prevent it. The new cable will start from Bahia Blanca, or some other point on the Atlantic seaboard, and link up with existing lines at Ascension Island, thus placing the country in direct cable communication with Europe. It is expected that the new route will be open for traffic next year.—The recent temporary breakdown in the Berlin telegraphic communication was principally due to the collapse of a tower on the roof of the General Telegraph Office under the weight of snow.

COMPANIES' MEETINGS AND REPORTS

SIEMENS & HALSKE, AKT.-GES., BERLIN.—A dividend of 12 per cent. is proposed for the business year 1908-9, as against 11 per cent. for the previous year.

AMAZON TELEGRAPH CO.—At the meeting last week the chairman said he regretted that during the past year the income had decreased and the expenditure increased. Steps were being taken to lay a new cable alongside the river, and the new issue of 5 per cent. debentures was mainly for that purpose.

WEST INDIA & PANAMA TELEGRAPH CO.—At the annual meeting last week it was stated that the loss on traffic for the half-year was £1,535, although the profit on working was £1,326 more than in the corresponding period last year. This, however, was due to the decreased cost of repairs.

MATHER & PLATT.—It is announced that the directors recommend the distribution of £200,000 from the reserve fund as a bonus, by the allotment of fully paid £1 ordinary shares to be issued in the proportion of five £1 shares in respect of each holding of an ordinary £10 share. It is also proposed to subdivide the existing ordinary £10 shares into £1 shares.

Siemens-Schuckert Meter.—The Board of Trade have approved of the pattern and construction of the Siemens-Schuckert meter for continuous current, type G.B., and also of the means provided for fixing same.

Wireless Telegraph Notes.—It is stated that a long-distance wireless telegraph record was set up last week, when communication was established between the Pacific mail liner *Korea* and the United Wireless Station at San Francisco, which was 4,700 miles away.

The Times states that the Swiss military authorities have recently been experimenting with mobile wireless stations in the Alps and the valley towns with curious results. The first two stations were established at Berne and at Ebikon, in the canton of Lucerne, about 35 miles apart, but communication could not be opened between these two places, whereas messages in English from Poldhu, in Cornwall, and in German from Berlin were received in numbers. The Berne station was transferred to Aigle, and the result obtained was somewhat better, but still unsatisfactory, and it is likely that the mobile wireless stations will be suppressed and a permanent station constructed at Thun in order to establish wireless communication with the military posts on the St. Gothard, Rigi, and the Fort of St. Maurice, which daily receive unsolicited messages from Europe.

MISCELLANEOUS CITY NOTES

AMAZON TELEGRAPH CO.—Subscriptions are invited until Monday for an issue of £300,000 five per cent. debentures in 3,000 debentures of £100 each at 98 per cent.

GALLOWAYS.—Mr. Charles Leonard Agnew has been elected chairman of the board.

COMPANIES STRUCK OFF REGISTER.—The names of the following companies will be struck off the register of Joint Stock Companies within three months unless cause is shown to the contrary:—Dorchester Electric Light and Power Co., Electric Canal Haulage Co., Birmingham Electrobus Co., Liverpool Electrobus Co., Manchester Electrobus Co., Nottingham Electrobus Co., Nottingham Gas and Electric Fittings Co., Provincial Electrobus Co., Richardson Electrical Co., Scottish Electrobus Co., Tramways Development Co., Midland Electric and General Engineering Co., and Pioneer Electric Light & Power Co. of China.

ALUMINIUM CORPORATION.—In the Chancery Division on Tuesday, the scheme for reconstructing this company, outlined in our last issue, was sanctioned.

Death from Electric Shock.—An inquest was held last week concerning the death of Robert Hall, a signalman in the Electrical Department of the Denby Colliery, who was killed through handling a cable in the pit. The jury returned a verdict of accidental death. A full report will appear in our Mining Supplement next week.

Collision on the District Railway.—A collision occurred on the District Railway at Ealing Broadway Station early on Friday morning. An empty train due at Ealing Broadway at 5.37 a.m. was running into the station, and for some reason was failed to be stopped, and came into collision with the buffers. Considerable damage was done to the station, and the train was badly wrecked. Unfortunately, the conductor on the car was killed almost immediately, and the driver died in the hospital later in the day from his injuries. It is stated that the brakes of the train were inspected before leaving the shed in the morning, and that the motormen have definite instructions to test the brakes on preparing for running. The inquest was opened on Saturday morning and adjourned until December 2nd. On Monday an inquiry was held by Major Pringle, on behalf of the Board of Trade, but this was conducted in private, the reason given being that the Inspector feared the witnesses would not give evidence quite as frankly as possible if they were apprehensive of it being published and possibly used against them at the adjourned inquest.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of **9d.** per line (column width).

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of **1/-** for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to THE KILOWATT PUBLISHING CO., LTD., 203-6, Temple Chambers, London, E.C.

Small Advertisements continued from p. viii.

By Order of the Receiver. *Re* **"Kupron, Ltd."**

MR. E. HUGH HENRY will Sell by Auction on the Works, Bromells Road, Clapham, on Tuesday, December 7th, 1909, at one o'clock precisely, the VALUABLE PLANT, MACHINERY, and STOCK of "Kupron, Ltd.," ART ELECTRIC METALLURGISTS, including 3-phase Alternating Motors of 7½ horse power, 3-volt Generators, volt and ampere Meters, 3 and 6 horse power Motors (Langdon-Davies), Air Pumps, Polishing Lathes, Bending Machines, vertical Drilling Machine, Metal-cutting Machine Lathe; turning up to 14-inch diameter, Band and Circular Saw and other machinery and tools. Weighing Machines, lead-lined and earthenware Tanks and copper fittings. Plating solutions. STOCK of ART METAL GOODS, including Statuettes, Busts, Plaques, Door Furniture, &c., and the Office Fittings, comprising three Safes, Roll Top Desk, Writing Tables, Typewriter, &c.

View day prior, and Catalogue of Messrs. Ball, Baker, Cornish & Co., 1, Gresham Buildings, Basinghall Street, E.C., and of the Auctioneer, 73, High Street, Clapham.

ELECTRIC INSULATING AND FRICTION TAPE. We want to get into communication with reliable concerns in position to handle our out-put of Insulating and Friction Tapes and Splicing and Liquid Insulating compounds. Our WALPOLE TAPE is acknowledged to be the best made, all tests. Can supply in any quantity. Address: WALPOLE RUBBER CO., Limited, Montreal, Canada.

ELECTRICAL ENGINEERING BOOKS AT HALF PRICES!! Books on Electrical, Engineering, Technical, *and all* other subjects supplied. Sent on approval. State wants. Catalogue No. 98, Post Free. Books bought. W. & G. FOYLE, 135, Charing Cross Road, London, W.C.

NEW SERIAL ISSUE.

Revised and Enlarged.

ELECTRICITY IN THE SERVICE OF MAN

BY

R. MULLINEUX WALMSLEY

D.Sc. Lond., F.R.S.E.

A popular and practical work on the application of electricity to modern life. It includes the complete history and principles of the science, the technology of electricity, and other details, definite facts and figures necessary to students and professional workers and all interested in the subject. The work contains a series of folding and full-page plates and

OVER 1,600 ILLUSTRATIONS.

THE WELSBACH METAL FILAMENT LAMP: ACTION BY GENERAL ELECTRIC CO.

IN the Clerkenwell Police Court on Saturday, Mr. Bros sat for the fourth time to hear the summonses taken out by the Wolfram (Tungsten) Metal Filament Lamps, Ltd., and the General Electric Co., Ltd., against the Welsbach Incandescent Gas Light Co., Ltd., for applying a false trade description to the metal filament lamps which they have recently put upon the market. Mr. Rufus Isaacs, K.C., M.P., Mr. H. A. Colefax, and Mr. E. Lunge are appearing for the prosecutors, and Mr. A. J. Walter, K.C., and Mr. A. H. Bodkin for the Welsbach Co. The previous hearings were reported in our issues for October 28th, November 4th, and November 11th.

Dr. Otto Oberlander, Consulting Chemist, and adviser to the Deutsche Gasglühglicht Aktiengesellschaft (Auer Gesellschaft), stated that he had examined the metal filament lamps sold by the Welsbach Co., and found that they were made of tungsten. He believed the makers were Messrs. Ehrich & Graetz, of Berlin. In his opinion there was no doubt that the impression produced upon the minds of electrical engineers in this country by the Welsbach Co.'s advertisement was that the lamps offered for sale were the invention of Baron Von Welsbach, and were manufactured by the German Auer Co., whereas they were not. In his opinion, Baron Von Welsbach could not lay claim to having invented a tungsten filament lamp, as none of his patents referred to such a metal. It was quite true that some of Baron Von Welsbach's patents referred to mixtures of osmium and other metals of the platinum group, but none of these specifications, in his opinion, would be capable of the production of a practical lamp.

In cross-examination by Mr. A. J. Walter, Dr. Oberlander expressed the opinion that Messrs. Just & Hanaman were the first patentees in England of the tungsten lamp. Mr. Walter thereupon drew his attention to patent No. 6,104 of 1889, in the name of Tibbetts, which made the following claim:—"An improved method or process for manufacturing filaments for incandescent electric lamps consisting of saturating a carbon filament with tungsten compound and reducing such compound to the metal tungsten," and witness agreed that this process was in part followed by Just & Hanaman, although their patents were of a later date. Mr. Walter also pointed out that a patent of Kellner, of 1898, also anticipated the Just & Hanaman patents, but Dr. Oberlander replied that this merely suggested wolfram, and had remained a suggestion ever since. He was not aware, he said, that any proceedings were being taken by the owners of the Just & Hanaman patents against the Welsbach Co. for infringement, nor against Messrs. Ehrich & Graetz in Berlin. Neither was it a fact that the present proceedings were being taken in the police court because the owners of the Just & Hanaman patents felt themselves unable to sue for infringement. The trade mark "Aur," continued Dr. Oberlander, was familiar to him in this country in respect of gas mantles and accessories, but certainly was not familiar in regard to electrical goods. He was not aware of any advertisement issued by the General Electric Co. of Osram lamps in which the word "Auer" was used, and it was true that in Germany the lamps were marked "D.R.P." (Deutscher Reichs Patent), in addition to the words "Auer Gesellschaft."

In re-examination by Mr. Isaacs, witness stated that in his opinion it would be impossible to make a practical lamp under the Tibbetts and Kellner specifications.

Mr. Walter:—A question which will be tried before another tribunal hereafter.

Mr. Duncan Watson, electrical engineer, 102 Charing Cross Road, London, gave similar evidence to the previous witness as to the effect upon the minds of electrical engineers of the Welsbach Co.'s advertisements. When he first saw the advertisement he telephoned through to Mr. Fletcher, of the General Electric Co., to ascertain if the lamps were Osram lamps. The general appearance of the lamp shown in the advertisement, combined with the words "Welsbach" and "Auer," had led him to think that the Welsbach Co. were selling Osram lamps under their name, as it was a custom for lamps made in one factory to be sold by different retailers under different names. In cross-examination, and being shown a specimen lamp, witness admitted that he would not mistake it for an Osram lamp, as it bore the words, "Made in Germany," and "Patent Applied For." The German Welsbach Co. was well known to him in this country as the Auer Co., but until these proceedings commenced he had never heard of the trade mark "Aur" in any connection whatever in this country. He believed that Baron Von Welsbach and the German Auer Co. were closely connected, and it was upon this that he based the opinion that the advertisement must produce the impression that the lamps were the invention of Baron Von Welsbach, and were manufactured by the German Auer Co.

The proceedings were again adjourned.

EXPERIMENTS ON FUSES

A PAPER by Mr. W. T. Maccall, describing some experiments on single and stranded fuses, was read before the Leeds Local Section of the Institution of Electrical Engineers on Wednesday, Nov. 17th. The author commenced by pointing out that the usual formula due to Sir William Preece, viz,. $C = k.D$ (where C = fusing current in amperes, D = diameter of wire in inches, and k = constant for any particular material) was not applicable to stranded wires, because the wires diminish each other's emissive power to an extent which can be determined only by experiment. All we can predict, he said, is that a two-strand fuse will carry less than twice the fusing current of either of its equal wires, and probably more than 1·41 times this current, and for a three-strand fuse the current will lie between thrice and 1·73 times that of the single wire, and so on.

The objects of these experiments were to determine the variations in Preece's "constant" (or in the emissive power) with change of diameter; to determine the effect on fusing current of house-service fuse-holders; and to find the ratios of the fusing currents of single and stranded fuses in the open and in fuse-holders.

For the experiments in air large terminals, $\frac{7}{8}$ in. diameter, with screws 0·44 in. diameter, were employed, with centres placed 3 in. apart. The fuse-holder employed was of porcelain, with copper end-pieces, to which the fuse was attached by nuts and washers. The experiments were confined to tin fuses in air and in this one type of fuse-holder, and dealt chiefly with single- and two-strand fuses. The wire contained 99·6 per cent. tin, and corrections were made for temperature.

The results for single wires corrected for an air temperature of 16° C. are given below:—

Diameter. Mils.	S.W.G.	In Air or Fuse-holder.	N.F.C. Amperes.	$10^3 \times E$.	$k \div 10^3$.
15·3	28	Air	3·58	2·60	1·89
21·9	24	,,	5·26	2·42	1·66
28·6	22	,,	7·53	1·77	1·56
15·3	28	Holder	4·58	4·27	2·42
21·9	24	,,	6·28	3·44	1·94
28·6	22	,,	8 17	2·08	1·69

The value for 28 S.W.G. in air is with fuse horizontal, all others with fuse vertical. The value of E (the emissivity) can be calculated either from the actual fusing currents or from the values corrected as above to an air temperature of 16° C. Preece's constant (k) is given for the diameter in inches. The values of E and of k decrease with increasing diameter, especially for fuses in holders; in fact, in the latter case, the N.F.C., instead of varying as $d^{\frac{3}{2}}$ does not vary even as rapidly as the diameter, but about as its 0·92 power. Again, in all cases a wire carries more current before fusing in a holder than the same wire in the air, but the increase is most marked for the smaller wires, the respective increases being 28 per cent., 19 per cent., and 8 per cent. This is only natural since the holder itself will radiate at about the same rate for each wire, which means a smaller percentage the larger the wire.

A similar table of two-strand fuses is given below:—

Diameter. Mils.	S.W.G.	Twists per inch.	In Air or Fuse-holder.	N.F.C. Amperes.	$10^3 \times E$.	$\frac{k}{10^3}$.
15·3	28	$3\frac{3}{4}$	Air	5·37	1·47	1·42
21·9	24	3	,,	8·85	1·37	1·37
28·6	22	2	,,	13·0	1·32	1·34
15·3	28	$3\frac{1}{2}$	Holder	6·37	2·06	1·68
21·9	24	$2\frac{3}{4}$	,,	9·38	1·53	1·44
28·6	22	$2\frac{1}{4}$	,,	13·4	1·52	1·39

The same general results are seen here as for the single fuses, except that k varies less, especially in air, probably because the results for 28 S.W.G. are less affected by its being placed horizontal than they are in the case of single wires. The increase in N.F.C. when fuse is placed in holder are 19 per cent., 5 per cent., and 3 per cent. respectively, again showing a diminishing effect with increasing size, and smaller effects than for the single wires.

The ratio of N.F.C.'s for single and double fuses varies from 1·39 to 1·73. A few experiments were made on three-strand fuses which give a N.F.C. of a little over twice that of single wires of the same size. It is hoped to complete these and to extend the results to fuses of other materials.

Mr. A. J. CRIDGE (Electricity Supply Department, Sheffield), in opening the discussion, considered that the subject was a matter more of academic interest than of popular application. In practice a man did not stop to calculate the exact gauge of wire necessary before inserting a fresh fuse, but acted according to his experience or the material at hand.

Digitized by Google

Mr. H. E. YERBURY (Corporation Tramway Manager, Sheffield) said the experiments were of value even if the results attained were not put into ordinary practice.

Mr. E. J. MARSH (Tramway Department, Sheffield) asked whether quickly switching on and off the increasing increments of current, in the case of fuses with holders, would result in a lower fusing current. The radiating effect of the holder, he should think, would not have sufficient time to reduce the temperature of the wire

Mr. T. W. SAMPSON (Sheffield) considered it contrary to what one might have expected that the holder had practically a constant value in reference to its effect on the fusing current, as the small wire would not be able to heat the holder to the same temperature as a larger wire. He should expect the value of Preece's constant to vary, as, while the current-carrying capacity altered as the square of the diameter, the radiating surface varied only as the diameter; therefore the value of K would alter with different diameters of wires. The emissivity varies as the circumference of the radiating surface.

Mr. F. WARDROBE (Sheffield) had made a large number of experiments with currents up to 600 amps. His results with single and two-strand wires agreed closely with those of the author; with three strands over two the ratio of the N.F.C. was 1·37, and with four over three the figure was about 1·2. He always used copper wire, standardised, and put the wires side by side.

The Chairman, Mr. W. M. ROGERSON (Borough Electrical Engineer, Halifax), had found in practice that aluminium gave the best results; there was not half the sparking or exploding as with either copper or tin. Copper fuses the whole length of the wire, and sometimes the holders as well, but with aluminium the fusing was confined to the wire itself with less explosive force.

A communication was read from Mr. H. L. JAMES (Technical College, Bradford), in which he noted that the results obtained by Mr. Maccall were in conformation with those of Prof. Schwartz and himself; he did not think that the most suitable form of fuse-holder had been chosen.

Mr. MACCALL, in replying, regretted he had not had the opportunity to extend his experiments to other metals. He pointed out that even if there was no twist in the wires, there would still be a reduction in the ratio of the current capacity of two wires over one. The only way to avoid it was to fix the wires so far apart as not to interfere with one another as regards radiation.

Naval and Engineering Exhibition.—Following the success of the Engineering and Machinery Exhibitions at Olympia in 1906 and 1907, it is announced that a Naval, Marine, and Engineering Exhibition is being organised for next September. A special electrical section will be included. The organising manager is Mr. F. W. Bridges (119-125 Finsbury Pavement, E.C.).

Development of Electric Traction.—In his presidential address before the Institution of Engineers and Shipbuilders in Scotland, delivered in Glasgow on Oct. 26th last, Mr. C. P. Hogg reviewed the development of the various methods of transport in the United Kingdom. Referring to tramways, he pointed out that of the 2,464 miles of tramways in the United Kingdom (1908 returns), 2,286 miles were operated electrically, 52 by steam, 28 by cable, 4 by gas-engines, and 94 miles were horse trams. There were, he said, 200 miles (single track) of railways partly, and 204 miles (chiefly London underground railways) solely worked by electric traction.

Arc Lamp with Fluid Electrodes.—A recent issue of the *Electrical Review and Western Electrician* (Chicago) contains a description of a new type of arc lamp invented by C. D. Haskins. The patent rights have been acquired by the General Electric Co., of America. In this lamp the electrode material, comprising a mixture of powdered coke, lampblack, anthracite, bituminous coal, and a suitable binding agent, is slowly exuded from two metal containers through tubes surrounded by heating coils. The material is baked into hard cylindrical electrodes during its passage through these tubes. The striking mechanism is of the usual pattern, and both electrodes are fed forward when the clutches are released, by the weight of the fluid material above them, or by springs or plungers acting on the material.

The Flicker Photometer.—A Paper on the physiological principles underlying the flicker photometer was read by Mr. J. S. Dow at a recent meeting of the Physical Society of London. The author described experiments which showed that the "yellow spot" and "Purkinje" phenomena which are a cause of uncertainty in photometers of the "equality of brightness" class, also occur with the flicker instrument, but in a much less marked degree. In the discussion, Mr. A. P. Trotter suggested that the action of the peripheral parts of the retina should be investigated by means of a photometrical device, covering a large field of view, but with the centre of the patch blocked out. The application of the rod and cone theory to the results of the experiments were also discussed. Mr. C. C. Paterson did not think that in making photometric comparisons, the area of the retina outside the yellow spot was used to any appreciable extent; he suggested that discrepancies were due as much, if not more, to psychological than to physiological causes.

MAGNETIC TESTING OF IRON AND STEEL

As already briefly noted in our last issue, Prof. W. Brown's inaugural address to the Dublin Local Section of the Institution of Electrical Engineers on November 11th took the form of an historical and critical review of the subject of magnetic testing. Not to mention Malen, who in 1861 made some observations on the magnetic susceptibility of iron, the first extensive experiments on the subject were made in 1870 by Prof. Rowland in America, and it was he who first showed that the permeability varied with the magnetisation, and employed the ballistic method, whereby the change in magnetic induction in the specimen for a given change in magnetising current is indicated by the effect of the transient current in a secondary coil of a ballistic galvanometer. Early important work was also done on thin wires by Mr. R. Shida (a Japanese gentleman), at Glasgow, in 1882, using the magnetometric method.

The most notable step, however, was the work embodied in Prof. J. A. Ewing's classical Paper of 1885, disclosing the phenomenon to which he gave the name hysteresis, and describing both ballistic and magnetometric methods of obtaining complete cyclic curves. A few months later Dr. J. Hopkinson published his work with the bar and yoke or divided bar ballistic method, in which a secondary exploring coil is suddenly jerked out of the magnetic circuit. Some difficulty was, however, experienced in getting good iron to iron contact. Hopkinson appears to have been the first to apply the term "coercive force" to the magnetic force required just to de-magnetise the sample. Prof. Ewing's well-known Hysteresis Tester, in which the deflection of a pivoted permanent magnet indicates the hysteris at one particular induction of a small rotating bundle of sheet samples, was introduced in 1895, and supplied a good rapid workshop method, sufficient to indicate if the sample is within the limits specified by the manufacturer. The Ewing permeability bridge for obtaining permeability curves of bar samples was brought out in the following year. In this, the sample is compared with a standard bar by adjusting the magnetic forces so that the inductions balance. In this instrument the effects of the airgap are fairly well got over, and the permeability curve may be quickly obtained with a minimum of calculation. The traction methods of S. P. Thompson, Du Bois, and Ewing were next described. In all these systems, the attraction between a fixed and a detachable portion of a magnetic circuit containing the sample is measured mechanically. The Thompson direct full "permeameter" has the objection of airgaps and doubtful iron contact, but has merits as a rough workshop tool. Of the magnetic balance type of magnetic tester, the Du Bois form makes use of an airgap, and measures the pull of the magnetised specimen across it, whereas in Ewing's balance the airgap is practically got rid of, and the iron contact is virtually reduced to a point where the bar to be tested lies across a slightly convexed pole piece. In 1901 Messrs. Lamb and Walker, of Cambridge, described an instrument in which the magnetic reluctance of the specimen is balanced against that of a variable airgap.

In all the instruments hitherto mentioned, specially prepared small samples are required. To enable large castings, &c., to be tested in bulk, Dr. C. V. Drysdale devised an arrangement in which a circular hole is drilled at a convenient point on the specimen, leaving a central pin, and an annular plug carrying magnetising and exploring coils is inserted. The head of the plug is conical, and forms a yoke to complete the magnetic circuit through the centre pin and the bulk of the material. The ballistic method is then employed. The system assumes that the condition of the iron is not altered by drilling, and that the material is homogeneous throughout, and Prof. Brown rather questioned its general utility.

In conclusion, some reference was made to the alternating-current method of measurement of hysteresis losses of Fleming and Beattie, which Prof. Brown considered to be of great use when once the apparatus was set up and calibrated, but had not time to discuss fully.

Direct Telephone Connection between Germany and Italy.—Negotiations are in progress for the establishment of telephonic communication between Frankfort-on-Main and Milan. It is proposed to run a direct line passing through the St. Gotthard tunnel, without any intermediate stations.

Wilful Short-circuiting of Transmission Lines.—The electricity works of Edenkoben, Germany, suffered considerable damage resulting in a cessation of supply for some hours, in consequence of the wilful short-circuiting of a 5,000 volt three-phase transmission line by an unknown person, who threw an iron wire over the high-tension conductors. The resulting current surge caused both a main switch in the station and also a line switch to burn out.

THE IMPORTANCE OF ATTENTION TO DETAIL

Mr. J. H. Rider's Address to the I.E.E. Students

ON Wednesday of last week, the present session of the Students' Section of the Institution of Electrical Engineers opened with an address by Mr. J. H. Rider, chief electrical engineer to the London County Council tramways, on the importance of details in engineering work. Attention to detail, said Mr. Rider, frequently meant all the difference, not only between success and failure, but between safety and danger. It was impossible to be a good designer without an intimate knowledge of the limitations of the manufacture and of the conditions of operation, and, in his opinion, nearly all the trouble which arose with plant in generating stations, which could be traced to causes other than inattention on the part of the operator, was due to the fact that the designers were good draughtsmen and very little else. It would be an excellent thing, Mr. Rider suggested, if every designer were to spend three months in every year in responsible charge of the erection and running of the plant which he designed, in order that he might learn the importance of attention to details. In order to lay stress on the necessity of a proper appreciation of the *relative* importance of details, Mr. Rider compared the trouble consequent upon the breakdown of a 5-h.p. chaff-cutter motor with that resulting from failure of a 5-h.p. motor employed for the purpose of removing the condensed steam from the condenser of a 5,000-kw. turbo set; in the latter case the importance of the motor was raised to that of the turbo-generator.

Referring to the purchase of auxiliaries from outside firms by a contractor, Mr. Rider pointed out that in sending in his tender the contractor generally selected the lowest price quoted him, without a proper regard to the effect of the auxiliaries on the working of his own plant. The consulting engineer might include in each specification only those articles which were made by the principal firms likely to tender, but if separate contracts were made, for example, for the turbine and generator of a turbo set, there would not only be the difficulty of arranging the relative responsibilities of the two contractors in the matter of erection, but the question as to which contractor was responsible for the efficiency of the set would become very complicated. The only practical course was to order both turbine and generator from the same firm, and it would be wise in some cases to accept a tender only from a firm which manufactured both. An engineer could, in most cases, only draw up a specification in general terms, and, as most public bodies would only accept the lowest tender, he was frequently saddled with second-rate plant, weak in its details, and a constant source of worry and expense.

After referring to the trouble resulting from unsuitable standard parts being worked into new designs, Mr. Rider gave a few illustrations, from his own experience, of the importance of details. Thus the contact pieces of a circular regulating switch in the excitation circuit of some alternators had no steady pins, and when the bundle of wires at the back were being straightened one day the contacts turned and touched, the voltage of the station rose, and considerable damage was done to lamps on the circuit. Field-coil connections of exciters were frequently made by means of connectors with tiny thumbscrews, and that was a constant source of danger. The main terminals of machines should always be protected. In one case the main terminals of a large generator were short-circuited by a chain hanging from a travelling crane, which was being hauled along the engine-room. The chain was welded to the terminals, the generator and engine were pulled up, and considerable damage was done. Switches had been found connected so that the blades were alive when the switches were open; fuses were placed where they would blow out into the attendant's eyes; circuit-breakers were fixed under instruments, so that the arc would inevitably damage the case, or so low that the arc would injure the attendant.

Mr. Rider then referred to the necessity for careful consideration of details in the design of steam-pipe arrangements, and to the consequences of neglecting the precaution of making all changes in the diameter of shafts, bolts, &c., subject to bending stresses, gradually by means of rounded fillets. He had had trouble due to neglect of this with the bolts in the cross-head of a vertical engine, with the valve opening rods of Corliss engines, and with the operating rods of some large throttle valves. Considerable economies in the working of steam plants could be effected by careful attention to the daily records of coal burned, water evaporated, &c., but every case had to be considered on its merits. In a station with a low load factor, expensive refinements to reduce the coal bill would not pay, as the extra wages and costs of maintenance and capital would outweigh any saving. On the other hand, with a high-load factor, the coal bill might be as high as 80 per cent. of the total costs, and it would then be false economy to stint labour or to omit refinements in the steam-raising plant. In this connection Mr. Rider referred to the Lea water recorder, which, he thought, could be the means of making great economies in many power stations, if properly and intelligently used.

Concluding, Mr. Rider said that while a good engineer was always characterised by a keen attention to matters of detail, it by no means followed that a man who watched trifles was necessarily a good engineer; the engineer should cultivate strongly a proper sense of proportion. The skill of the engineer was shown by his ability to distinguish between what was necessary and what was not. But, when it was decided what was necessary, its details should have all the care and attention which it was possible to give.

REVIEWS OF BOOKS

Berechnung und Konstruktion elektrischer Schaltapparate. By Prof. R. Edler. Vol. VII. of Grundriss der Elektrotechnik. Edited by A. Königswerther. 436 pp. 5¾ in. by 8½ in. 392 illustrations. (Hanover: Dr. Max Janecke.) 12 marks.

THIS book is suitable for advanced students of electrical engineering, but more especially for engineers specialising in the design and construction of switchgear, as the theory and design of switches, motor-starters, and other apparatus is treated with the thoroughness and wealth of detail so characteristic of German works of this nature. A knowledge of the working of electrical machinery and of the possible contingencies and accidents to be avoided is assumed, as is also a grasp of mechanics and dynamics, and a knowledge of workshop methods in construction. Although the subject is dealt with from the theoretical point of view, the connection between theory and practice is shown by numerous sketches and photographs of modern apparatus, and a number of curves and worked examples are included. Switchboards, and the arrangement and connections of switchgear in large power systems, are not dealt with in this volume which concerns only the separate pieces of apparatus. The chapters on motor-starters occupy over one-third of the book, and a long section is devoted to the design and construction of solenoids and electromagnets for automatic switchgear. A tremendous amount of valuable information is compressed into this volume, but there seems to be rather an unnecessary proportion of theory, which makes it hard reading. The diagrams are good, and the text also is illustrated with well-chosen examples of modern apparatus by German manufacturers.

The Tutorial Physics. Vol. I. A Text-book of Sound. By Edmund Catchpool. (Fifth edition.) 380 pp. 7 in. by 4¾ in. 148 illustrations. (London: University Tutorial Press, Ltd.) 4s. 6d.

ALTHOUGH the first edition of this book was published fourteen years ago, the present views and theories of the phenomena associated with the physical sensation of sound have not altered appreciably since then, and the successive revisions of this work, of which the present volume represents the fifth, have consisted chiefly of additions only. A large number of experiments with full descriptions of apparatus, and a collection of numerical examples, have been included in this last edition. A certain number of formulæ have also been introduced, although in the original editions mathematics were almost rigidly excluded. For telephone engineers and others whose stock of knowledge should include an acquaintance with the phenomena of sound, this book should prove of value; but it is written primarily for those studying for the intermediate and final university examinations. The book is scientifically sound, and presents a clear picture of all the physical processes concerned. It is well arranged and sub-divided, and a large number of helpful sketches and diagrams are included.

The Apprentices' Course of Experimental Physics and Mechanics for Preliminary Technical Students and Secondary School Pupils. By J. L. Maxim. 112 pp. 6¾ ins. by 4½ ins. 51 illustrations. (London: Longmans, Green & Co.) 1s. 6d.

AN elementary course of experimental physics is here given, including preliminary exercises in measurement and determination of densities, and simple experimental illustrations of the laws of mechanics and heat. The book is intended primarily for apprentices preparing for the preliminary technical examinations of the Lancashire and Cheshire Union of Institutes, and other elementary examinations. Electrical matters do not form part of the scheme. The instructions are concise, clear, and suggestive.

The "Mechanical World" Pocket Diary and Year Book for 1910. 390 pp. 6¼ in. by 4 in. Illustrated. (Manchester: Emmott & Co.). 6d.

THE twenty-third annual issue of this well-known pocket-book of mechanical engineering bears evidences of a good deal of revision, especially as regards the section on gas and oil engines, which has been revised and added to by Mr. W. A. Tookey. New subjects introduced include the design of centrifugal pumps, which is dealt with by Mr. B. M. Woodhouse, and ball bearings. Electrical matters are not dealt with, but are reserved for a companion volume. We are pleased to see that a new quality of paper has been adopted since the last issue.

DANGER OF SHOCK FROM LIVE TROLLEY STANDARDS

ATTENTION was drawn to the fact that the trolley standard on the open deck of a tramway car, in spite of careful insulation, is liable to become alive through accidental causes, with considerable danger to passengers unless proper precautions are taken, in a circular letter from the Board of Trade, mentioned in ELECTRICAL ENGINEERING of last week (page 982). On many cars the trolley standard is fixed at a short distance from the handrailing, so that it is possible for a passenger to place one hand on the vertical part of the standard, or one foot on its base, while at the same time the other hand is in contact with the railing. As the handrailing is metallically connected to the truck and through it to the rail, it is obvious that, should the trolley standard be alive due to an accidental connection with the cable from the trolley wheel which lies within it, a passenger in the position described would receive a shock of 500 or 550 volts across the body, with possibly fatal results, as was the case not many months ago in the Midlands.

The question naturally arises, how can such accidents be prevented and the safety of the passengers ensured. One solution of the problem is to provide a signal on each car which will instantly come into action when the trolley standard becomes alive. Various arrangements of this kind have been tried, but have been proved more or less unsatisfactory and liable to failure. A system introduced by the British Thomson-

BELL INDICATOR FOR LIVE TROLLEY STANDARDS.

Houston Co. merits attention as presenting some distinct advantages. This arrangement ensures that, immediately the trolley standard becomes alive, an audible signal will be given by the ringing of a special type of electric bell, and simultaneously by the lighting up of two red lamps fixed above the car platforms. These signals are independent of each other, so that the failure of one cannot interfere with the proper working of the other. This system, moreover, is entirely automatic in action, and does not require a battery or any mechanical gear for its operation, nor does it in any way interfere with the running of the car. This provision of two distinct, independent and automatic signals, one audible and the other visible, fully meets with the recommendation of the Board of Trade. An interesting feature of the system is the construction of the leakage indicator or bell which is designed to work on 500 volts. This special type of bell, as may be seen from the illustration, is completely enclosed in a metal case and adapted for fixing under the canopy, where its warning can be instantly heard by the driver or conductor.

We understand that the B.T.-H. leakage indicator has been in successful use for the last five years in the tramways at Scarborough and Leith, and also at Dunfermline, where it has given thorough satisfaction. By equipping tramcars with this inexpensive system, tramway managers safeguard their patrons from the possibility of shock and themselves against heavy damages.

Obituary. The death is announced of Mr. Arthur Henry Wright Radcliffe, who was well known in electrical circles in the early 'eighties. He was originally in the service of the Electric Telegraph Co., and demonstrated the use of the telephone in conjunction with Mr. Graham Bell, and the late Mr. Lawson Tait, in Birmingham, in 1877. Mr. Radcliffe was born in Chorley in 1836. During the Indian Mutiny he was for some time at Windsor Castle in charge of a telegraph installation which had been placed there for the use of her late Majesty Queen Victoria.

THE DEATH OF A GUARD ON THE DISTRICT RAILWAY

ON Thursday, Mr. Walter Schroeder, deputy coroner for West London, held the adjourned inquest upon C. Sargent, a guard in the employ of the Metropolitan District Railway Co., who was found dead in an electric locomotive on November 9th at Gloucester Road Station. On the date in question a District "Circle" train, at the head of which was an electric locomotive, working in conjunction with motors in other parts of the train, had arrived at the station, when the driver noticed that one of the "'bus line jumpers" (a flexible connection between the locomotive and the rest of the train) was burning in the receptacle box. He pulled out the main knife-switch on the panel inside the locomotive, and interposed pieces of wood between the negative shoes and the central conductor rail at the back and front of the locomotive. He was unable to do this to the positive shoes on the outer rail, owing to their being close to the platform. His attention was then called to the deceased, whom he had just previously asked to get the passengers out in order to have the train shunted, and found him lying on the floor of the locomotive. There was no current on the motors, and all the apparatus in the locomotive was quite dead. Further, the deceased had climbed into the locomotive from the six-foot way, *i.e.*, the opposite side from the positive rail. Again, all the electrical apparatus in the cab was on the opposite side from the six-foot way, and away from where the deceased was found. Dr. Parsons, of St. Mary's Hospital, expressed the opinion that the deceased must have died from electric shock, as, from a postmortem examination, he saw nothing to attribute death to any other cause. He admitted there were no signs of burning or scorching on the body, but the skin hæmorrhages were more numerous than in ordinary cases of death from natural causes. He thought the shock had been received in the head, and it was quite possible for this to happen without injury to the scalp. Mr. W. A. Agnew, mechanical engineer to the Metropolitan District Railway Co., said that from his examination of the locomotive, the trouble had originated in the rear 'busbar receptacle on the positive side, and that an arc had been maintained between the positive and negative conductors. The cable leading from the rear positive shoe on the platform side had fused through, but the rest of the equipment was in proper order. There were no faults or damage inside the locomotive. If, as the motorman said, the main switch was out, then the whole of the electrical controlling mechanism would have been cut off. Accepting the driver's evidence, he could not believe that the deceased had received an electric shock. The only live part would have been the damaged 'bus-line box outside, and to reach this required an effort. It would also be possible to touch the brush-holders of the air-compressor motor in the cab, but this, he understood, was not working at the time, and in any case, the deceased was found several feet away from both. Mr. Agnew said he had come to the conclusion that it was unlikely that the deceased received an electric shock, an opinion arrived at, we understand, after consultation with Mr. A. P. Trotter, electrical adviser to the Board of Trade, who has examined the locomotive. This, however, was not admitted as evidence. He agreed with Mr. Arthur Newton, who appeared for the relatives of the deceased, that it was practicable to enclose the brush-holders of the air-compressor motor.

Guided apparently only by the medical evidence, the jury returned a verdict that death was due to shock from electricity accidentally received, and added a rider that the brush-holders should be protected. This relates to the air-compressor motor, which it was not denied had nothing to do with the case, as the deceased was found some distance away from it. Perhaps the report by the electrical adviser to the Board of Trade, which will be published in due course, will throw more light on the matter. Beyond the evidence of the mechanical engineer to the District Railway Co., no attempt seems to have been made to secure expert evidence, although the inquest had been adjourned for this purpose. No possible explanation was given as to the manner in which the deceased received a shock. The whole of the circumstances would appear to require further investigation.

Engineering Exhibition at Manchester.—Our contemporary, the *Engineering Review*, informs us that it is organising an Engineering and Machinery Exhibition, to be held at the new City Exhibition Hall, Manchester, from October 14th to November 5th, 1910. Applications for space may be addressed to Mr. C. H. Luke, at the Exhibition Offices at 16 John Dalton Street, Manchester.

The Crystal Palace Tube Railway.—The Sydenham, Victoria & West End Electric Tube Railway Syndicate announce that although matters relating to the Crystal Palace Tube Railway are progressing satisfactorily, they have decided, owing to the present state of public and financial affairs and the near approach of the appeal to the country, not to proceed with their Bill until after the General Election.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

HOLOPHANE GLASSWARE.—A new list containing particulars of these deservedly popular shades, globes, and reflectors is being issued by the Holophane Glass Co. (12 Carteret Street, Westminster). Owing to the correct optical principles upon which these are designed, a maximum degree of evenness of illumination and absence of glare can be obtained by their use with a minimum loss of light, and by suitable selection from the variety of patterns made, the light can be concentrated or diffused in accordance with almost any requirements. The globes are generally constructed with a series of horizontal prisms on their outer surface for redirecting the light rays, and a series of internal prisms which follow the law of cosines to give perfect diffusion. A new form of holophane globe has now been constructed in which radial flutes are employed, giving to the globes all the sparkle and brilliancy of cut glass with the advantage of scientific light diffusion and distribution. The external prisms, which form horizontal rows from top to bottom of these globes, are designed to re-direct the light rays by both reflection and refraction. No two of these prisms are alike, and each is accurate to one-thousandth of an inch. These outside prisms generally consist of four independent surfaces, the angles and inclinations of which are perfectly calculated to give the predetermined distribution of light rays. Holophane glass reflectors form a group distinct and separate from the globes above described and are constructed upon an entirely different principle. The outer surface is substantially covered with total or double reflecting prisms calculated to reflect the light rays back through the body of the glass and out of the open mouth of the reflector. The inner surface of the reflectors can be altered to produce different effects, and the most common of these is by enamelling or satin finishing the inner surface. The use of metal filament lamps of high intrinsic brilliancy has given particular impetus to the demand for this style of apparatus. Several new ornamental patterns have been introduced, but none of the patterns listed can be classed as inartistic.

ARC LAMP CARBONS.—A list is to hand from Messrs. H. G. Mayer & Co. (67 Aldersgate Street, E.C.) of Plania carbons of various qualities and descriptions for ordinary enclosed and flame arc lamps and projectors.

MOTOR-CAR HEADLIGHTS.—A pamphlet from the Cowper-Coles Engineering Co., Ltd., describes a form of lamp which the company have developed. These are suited for use either with electric lamps or acetylene, and a beam of specially penetrating power without "dazzle" is obtained by the use of gold as well as silver in the mirrors. The gold gives a preponderance of yellow and red rays, but eliminates most of the violet rays which dazzle and are painful to the eyes.

METACASE WIRING.—A list from the Sun Electrical Co. (118-120 Charing Cross Road) gives a full description of the wiring system employing "Kuhlos" and "Stannos" "Metacase" conductors and "Kalkos" fittings, and known as the O.S. wiring system. The latest developments of the system were described in ELECTRICAL ENGINEERING, October 28th, page 934.

FEEDER PILLARS.—British Insulated & Helsby Cables, Ltd., have sent us a copy of a new edition of their copiously illustrated pamphlet describing the various forms of the "Prescot" feeder pillar, made under Downe and Black's patent. In these well-known pillars the actual feeders and distributing cables are brought direct to the fuse terminals on the face of the panels, effectively sealed in position, and isolated from all the remaining cables in the pillar. Each set, postive, negative, and neutral, forms a complete and separate unit, and can be removed complete without in any way disturbing the rest of the connections.

ACCELEROMETER AND GRADIENT MEASURER.—A new instrument, designed by Mr. H. E. Wimperis, is described in a leaflet from Messrs. Elliott Brothers (Century Works, Lewisham). The apparatus enables direct readings of accelerations of vehicles, if on a known gradient, to be made, or the gradient to be measured if the vehicle is moving uniformly or is at rest. From these readings a number of determinations of tractive forces and resistances, &c., may be made. Inside the instrument there is a horizontal copper disc having an eccentric centre of gravity. This disc is controlled by a light spring similar in shape to the hair spring of a watch, and is "damped" magnetically. When the instrument is caused to move forward in the direction of an arrow shown on the dial, the centre of gravity of the disc tends to lag behind and so rotates the disc through an angle controlled by the spring. This motion operates the indicating needle and the scale is graduated accordingly. Each instrument is "compensated," so that accelerative forces in any other direction than that shown by the arrow do not affect or interfere with the reading in any way. This "compensation" is produced by the use of two freely running gear wheels and a balance weight so calculated as to form a dynamic balance with the disc. The accuracy of each instrument is very carefully tested before it is sent out.

RADIATORS.—A sheet of illustrations of lamp pattern radiators is being circulated by the Sun Electrical Co. (118 and 120 Charing Cross Road, W.C.). This forms advance pages of the company's new large radiator catalogue, which is now in the press, and will contain illustrations of a large number of new and artistic patterns.

SIMPLEX CONDUITS AND ELECTRICAL SUPPLIES.—We have just received a copy of the new edition of the complete bound catalogue covering all the lines in which Messrs. Simplex Conduits, Ltd., are now dealing. The list comprises some 400 pages, with over 1,500 illustrations, and appears to include every type of accessory required for complete lighting installations. We have already reviewed certain sections which have been issued separately. The portions dealing with electric heating and cooking have been much extended, and include a long range of apparatus on the Prometheus system, for which the company are sole agents. The sections on conduits and fittings and on the Simplex flexible wiring system are, of course, important features, and the portion dealing with distribution boards is particularly complete. A considerable portion of the catalogue is devoted to electric light fittings, and endeavour has been given to include the widest possible range, both as regards style and design, variety and price. For instance, electroliers have been listed from 10s. each to £60. In this section mention should not be omitted of the effective coloured plate illustrating the firm's "Spookie" shades. More recent development of the company's business is included in the form of electricity meters; 15 separate types of meter are listed, including those for the two-rate system of charging with suitable time switches. Other sections deal with special water-tight fittings, wires and cables, installation accessories, bells, porcelain insulators, carbon and metal filament lamps, fans, and small motors and electrical signs. We are requested to state that a copy of the catalogue will be sent to any member of the trade on receipt of a post-card, and that all the sections can be had separately bound, if this is found more convenient.

TANTALUM LAMPS.—A further addition to the foreign series of tantalum lamp show cards has been issued by Messrs. Siemens Bros. Dynamo Works, in the shape of an attractive design with a German inscription.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

IN the *Oil and Colour Trades Journal* of November 13th, there is an interesting note upon Bleach *versus* Electrolytic Chlorine. The title is not quite correct, because what is meant is the relative efficiency of a bleaching powder solution, calcium hypochlorite, and a bleaching solution produced by the action of the electric current upon a solution of sodium and magnesium chloride. Experiment has shown that using equal amounts of active chlorine (the strength of a bleaching solution always depends upon the amount of active chlorine), the electrolytic bleaching liquor gives the better bleaching effect. By stopping the bleaching effect at the same degree of whiteness, the electrolytic bleaching liquor shows a saving of 5 per cent. of chlorine, when working with alkaline solutions. The comparative results are not altered by employing an excess of bleaching liquor. The actual economy may be small by employing electrolytic bleach, but for bleaching wood-pulp and cellulose, the electrolytic liquor gives the better results. The author of these notes has found that in laundry work electrolytic bleach is much superior to solutions of bleaching powder, or to solutions of sodium hypochlorite prepared from bleaching powder.

In the *Zeitschrift für Elektrochemie* of October 1st, there is an article by Dr. Amberg-Bodio upon the form of silicon carbide, known as silundum. This is prepared in a similar furnace to that employed for the manufacture of carborundum or graphite. Silundum appears to be a silicon carbide which contains more silicon than carborundum, is less crystalline in structure, and is a very much better conductor of electricity. It is possible to take carbon rods or articles of carbon, such as graphite crucibles, and by subjecting them to the vapour of silicon, either wholly convert them into silundum, or only convert the outside into this material—a sort of case-hardening. This substance appears to be a good conductor of electricity, its resistance being about six times that of carbon at ordinary temperatures. The resistance, however, only increases slightly with rise in temperature. It may be heated to 1,600° for a very long time without showing crystalline structure, but if heated for some time above 1,700° it commences to give off vapour of silicon. Silundum may be heated to white heat and then be plunged into cold water without fracturing. Owing to its conductivity and the fact that it is very difficult to act chemically upon it, it can be satisfactorily employed in the electrolysis of metals. It has been made into tubes, crucibles, muffles, and bricks for furnace purposes, and has been found extremely useful for such purposes. The substance is also a useful deoxidising agent, as it readily dissolves in molten iron, and apparently can be prepared with varying quantities of silicon.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 18th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

23,005/08. **High-Speed Wireless Telegraphy.** R. A. Fessenden. An ordinary Wheatstone transmitter is so connected with a system generating continuous waves that the perforated tape is caused to change the frequency of the waves without interrupting their continuity. Messages are sent at the rate of 500 words per minute, and are taken up by a suitable receiver which gives out sound signals. The sounds are recorded by a phonograph, which afterwards reproduces the messages slowly. Four claims, two figures.

23,39[illegible]/03. **Electrical Propulsion of Ships and Vehicles, &c.** W. P. Durtnall. Various methods of obtaining polyphase currents of different frequencies from one or more alternators running at a constant speed, are described. Among these is a system including a generator with two rotating elements, and also the so-called "Paragon" system, in which a number of induction machines are connected in cascade, each supplying a current of different frequency. (See Electrical Engineering, September 9th, 1909, p. 799.) Twelve Claims, seven figures.

23,515/08. **Automatic H.-T. Switchgear.** M. B. Field and Ferranti, Ltd. In order to reduce the size of the transformers and trip-coils for operating large circuit-breakers, a mechanical gear is interposed between the tripping device and the releasing catch, so that little power is required. The current transformers are combined with the insulators, through which the main conductors pass into the switch case. Both electromagnetic and hot-wire releasing devices are described. Eleven claims, fourteen figures.

27,729/08. **Ceiling Rose.** F. G. Bazell and R. B. Verney. Two screw clips at the ends of terminals passing through the body of the fitting, slip over bared portions of the main wires which are not cut. The flexible is attached by screws at the inner ends of the terminals. The base-plate, which takes the place of the ordinary wooden block, has recesses for the main wires and another recess to take a rib on the body, and one large screw passes through body and base-plate into the ceiling. Three claims, three figures.

28,351/08. **Motor Controllers.** R. F. Baerlocher. In controllers of the oil-immersed pattern, the drum is arranged to rotate about a horizontal axis. The drum, contact fingers, and operating mechanism are mounted on the lid of the oil tank. Switches interposed between the contact-fingers and the terminals at the bottom of the tank connected to the incoming leads, are closed only when the lid of the tank is closed. This construction renders inspection of the moving parts both easy and safe. Two claims, three figures.

28,561/08. **Electrolytic Meters.** W. B. Thorpe. A device comprising two electrolytic cells, with electromagnets working differentially on a single registering mechanism, is described. The method of igniting the evolved gases, and other details, are similar to those adopted in the meter described in Electrical Engineering, October 14th, 1909, p. 891. The present arrangement is stated to give correct readings with very wide variations in the supply pressure. Seven claims, seven figures.

3,588/09. **Electric Driving of Rolling Mills.** Soc. Anon. D'Ougrée-Marihaye and F. Courtoy. The motor is separately excited from a flywheel set, comprising a shunt-wound generator and a compound-wound motor. The generator excitation is automatically increased when the main motor current tends to increase, so that the back E.M.F. of the rolling-mill motor is raised, and its tendency to take a heavy current reduced. The flywheel prevents the too rapid interruption of the excitation current. One claim, one figure.

7,113/09. **Automatic Motor Control.** A. S. Cubitt. A motor-control system, in which the successive resistances are cut out automatically by contactor switches, to prevent too rapid acceleration of the motor. (See also Electrical Engineering, October 21st, 1909, p. 911.) Five claims, four figures.

Opposition to Grant of Patents

20,915/08. **Metal Filaments.** T. McKenna (*Gluhlampenwerk Anker-Ges.*). Opposition to the grant of this patent has been entered. The specification, abstracted in Electrical Engineering, Nov. 4th, 1909, page 950, describes a method of fixing filaments to leading-in or supporting wires which consists in electrolytically depositing a soft metal covering on the ends of the filaments before fusing with the blow-pipe.

22,964/08. **Lamp-Shade Gallery.** S. Falk (Falk, Stadelmann & Co.). The opposition to the grant of this patent has been withdrawn. (See Electrical Engineering, Aug. 26th, 1909, page 768, and Oct. 7th, page 888).

9,851/08. **Railway Signalling.** A. J. Poult (*Union Switch & Signal Co., U.S.A.*). In spite of opposition, the grant of this patent has been allowed. The specification describes a method of block signalling with electrically continuous rails. (See Electrical Engineering, May 31st, 1909, p. 452.)

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Chloride Electrical Storage Co. and Imbery [Automatic switching in of auxiliary source of power on failure of main supply] 16,285/08; Lamkin and Nunwick [Wiring system] 23,413/08; Strode [Wiring conduit] 28,127/08; Mansfield [Cable junction and inspection boxes] 28,397/08.

Dynamos, Motors, & Transformers: Derain [Constant pressure, varying speed generator] 4,837/09; Allgemeine Elektricitats Ges. [Control of polyphase motors] 17,758/09; Siemens Bros. Dynamo Works (*Siemens-Schuckertwerke Ges.*) [Cooling of machines] 22,789/09.

Electric Ignition: Harris [Safety device for electric detonators] 225/09; Simms Manufacturing Co. [Contact breaker] 1,641/09; Smith [Ignition apparatus] 3,469/09.

Heating & Cooking: Ponzini [Fluid-heater] 15,786/09.

Incandescent Lamps: Stearn and Topham [Series lamps] 4,694/09.

Switchgear, Fuses, and Fittings: Veritys, Ltd., and Pipkin [Circuit-breaker] 25,333/08; Curtis, Mackley, and Adams Manufacturing Co. [Switches] 4,111/09; Electric & Ordnance Accessories Co. and Collins [Time-limit device for circuit-breakers] 7,276/09; Sheehy [Fuse boxes] 10,796/09; Lundberg [Switches] 11,605/09; Backman [Switch-boxes and wall-plugs] 14,062/09; Siemens-Schuckertewerke-Ges. [Fuses] 14,622/09.

Telephony and Telegraphy: Fessenden [Oscillation generator] 18,430/08, and [Wireless signalling] 20,466/08; Marconi and Marconi's Wireless Telegraph Co. [Receivers] 4,125/09; Webb [Telephone receivers] 15,657/09.

Traction: Butterworth and Veevers [Electrically-operated tramway points] 23,546/08; Lecoche [Magnetic power transmission gear] 23,796/08; Coan [Signalling] 256/09; Taylor [Signalling] 15,978/09.

Miscellaneous: McClelland [Interrupter] 23,870/08; Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*) [Condensers] 13,135/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Electrochemistry: Langbein-Pfanhauser-Werke Akt.-Ges. [Production of ductile electrolytic iron] 24,841/09.

Telegraphy and Telephony: Valoris [Wireless telegraphy] 10,876/09; Willis [Telephone receivers] 24,583/09.

Traction: Russell and Lord [Splicing ear] 11,209/09; Hansen [Signalling system] 25,129/09.

Patent Amended

16,968/07. **Adjustable Carbon Powder Resistance.** H. S. Martin. Leave has been granted to the Electrical Regulators & Economisers, Ltd., to amend this specification. (See Electrical Engineering, Sept. 30th, 1909, page 859, and Oct. 21st, 1909, page 912.)

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distribution Systems, &c.: British Thomson-Houston Co. (*W. le R. Emmet*) [Insulation of conductors] 13,969-73/00.

Dynamos, &c.: British Thomson-Houston Co. (*E. W. Rice, U.S.A.*) [Rotary-converter connections] 13,967/00; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Series A.-C. commutator motor] 17,019/04, [Ventilation of field magnets and armatures] 15,860/05, and [Equalising rings] 15,860A/05.

Electric Ignition: J. T. Testor [Electric control of gas lamps] 17,181/04; A. E. Lamkin [Sparking-plug] 15,880/05; A. L. Davis [Commutators] 16,079-80/05.

Heating and Cooking: British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Electric soldering-iron] 15,769/05.

Incandescent Lamps: V. F. Feeny (*Allgemeine Elektricitats Ges.*) [Heaters for Nernst and similar lamps] 13,892/00.

Switchgear, &c.: G. H. Whittingham [Switches] 13,873-4/00; Siemens-Schuckertwerke-Ges. [Induction-motor starters] 14,211/05; L. Robinson & Co. and J. D. Adams [Time element for circuit-breakers] 15,819/05; G. O. Donovan [Switch boxes with interlocked covers] 15,871/05; J. R. Craig [Motor starter] 16,063/05.

Telephony and Telegraphy: British Thomson-Houston Co. (*W. le R. Emmet*) [Paper-insulated telephone cables] 13,969/00; C. Lean (*Deutsche Telephonwerke, R. Stock & Co. Ges.*) [Telephone system] 16,024/05.

Traction: W. Brierley [Signalling] 18,296/97; S. B. Apostoloff [Apparatus for testing vehicles] 16,921/04; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Multiple-unit control system] 17,016-7-8/04; A. Welsh [Trolley wheel] 17,207/04; M. Belmondo [Brake handle] 15,752/05.

SUMMARY

Our monthly supplement, "Electrical Engineering in Mines," is included in this issue. A short note introduces the subject of electric colliery winding, and in one of the articles some typical electric winding plants are described. A report is also given of a prosecution of mine managers in Scotland for alleged contravention of the Special Rules for Electricity in Mines. Some interesting patents relating to electrical mining work are reviewed, and illustrated descriptions are given of electrically driven air compressing and ventilating plants. The unusual circumstances which led to a death, by electric shock, at the Denby Colliery are related.

A service of electric trains was commenced yesterday on the section of the London, Brighton & South Coast Railway from Victoria to London Bridge. Some particulars of the system were given in our last issue, and we hope to publish a detailed description at an early date.

Electrical firms are being invited to exhibit at the Japan-British Exhibition. Mr. W. M. Mordey has accepted the Chairmanship of the Electrical Section, and Dr. Gisbert Kapp the Vice-Chairmanship. (Page 1017.)

The Paper read recently by Mr. C. A. Ablett before the Institution of Engineers and Shipbuilders in Scotland on electrical driving of reversing rolling mills was discussed at Glasgow last week. Mr. Lamberton, although admitting the advantages of electrical drive for continuous rolling, was sceptical as to the capital expenditure required for an Ilgner installation being justified. Mr. T. Mackenzie gave figures to show the saving in costs obtained in a German mill by the adoption of electrical working, and the economy in boiler power was demonstrated by Mr. S. A. Simon. Some other engineers also spoke. (Page 1017.)

The Scherl mono-rail gyrostat car recently exhibited in Berlin weighs about 3 tons, and can carry six passengers. It has two 2-wheel bogies, one wheel of each being geared to a 2-h.p. motor supplied at 110 volts from contact wires adjacent to the rail. The stability mechanism comprises two gyrostats rotating in opposite directions in a vacuum, and each driven at 7,000 r.p.m. by a ½-h.p. motor. Artificial acceleration of the precession is obtained by means of an apparatus worked by oil under pressure. (Page 1018.)

An interesting case was decided last week, in which a patient recovered damages from the Dowsing Radiant Heat Co. for burns received during high frequency treatment. The burns were caused by sparks from a metal braid on the patient's dress. (Page 1019.)

We conclude this week our list of Bills of electrical interest which are to be promoted in the next session of Parliament. (Page 1019.)

A letter signed by six members of the Special Committee of the Bradford Engineering Society appointed to consider the electrical driving of textile factories protests against the recently published report being described as the official report of the Committee,

Digitized by Google

and asserts that it was published without their knowledge or approval, and was not discussed by the whole Committee. (Page 1019.)

A GERMAN patent relating to arc lamps without feeding mechanism, and owned by the Deutsche Beck-Bogenlampen Gesellschaft, has been revoked by the German Patent Office at the instance of the Regina Bogenlampenfabrik, against which company an action for infringement had been brought by the Beck Co. One of the Regina Co.'s lamps, the "Conta" lamp, as the Beck lamp, has no feeding mechanism. (Page 1019.)

MESSRS. WILLANS & ROBINSON have secured the contract for two 4,000-kw. turbo-alternators for the Sydney Corporation. There was a difference of opinion between the Corporation and their engineer about the speed for these sets; the speed is to be 750 revs. per min., as originally recommended by the engineer. (Page 1019.)

IN a Paper read before the Institution of Mechanical Engineers recently, Mr. H. A. Humphrey described a new apparatus in the form of an internal combustion pump, and referred to its possible application in conjunction with water turbines for electric power stations. He estimated a consumption of 2 lb. of anthracite coal per kw.-hr. generated, allowing for a water turbine efficiency of 80 per cent. The possibility of hydraulic storage was also referred to. (Page 1020.)

AN application is to be made for an extension of the Marconi patent No. 12,039 of 1896. The Cape Town Legislative Assembly has sanctioned the expenditure of £10,000 for the erection of a wireless telegraph station. The Australian Government are seeking expert advice as to whether they should confine themselves to the Marconi wireless telegraph system, or should invite tenders from other companies. (Page 1020.)

A SOLDER for aluminium which requires no flux has just been placed on the market. Some very satisfactory tests have been made. (Page 1020.)

THE Aberdeen Corporation propose to take counsel's opinion with regard to the supply of electrical energy to the local tramway company.—The Sydney Council's electrical engineer has reported in favour of metal filament lamps for side-street lighting, but recommends flame arc lamps for main thoroughfares.—The construction of tube railways in Toronto is under consideration. A sub-committee has been appointed by the Glasgow Corporation to organise an exhibition of the most up-to-date appliances in electricity and gas in order to assist the campaign in favour of smoke elimination.—The Marylebone Borough Council propose to charge 1d. per unit for any supply at 100 per cent. load factor.—Newcastle Corporation have refused to appoint a Conciliation Board to deal with the tramway men's grievances. (Page 1021.)

LOANS for electrical extensions have been granted as follows: Dublin, £75,000; Aberdare, £17,000; Bridlington, £5,000. Local Government Board inquiries have been held at Walsall (£35,000), Wolverhampton (£10,000). The London County Council require tenders for equipping the Woolwich-Eltham tramways on the four-wire system. A large supply of incandescent lamps is required by the Melbourne City Council. (Page 1022.)

IN a Paper read before the Institution of Electrical Engineers on Thursday by Messrs. H. W. Handcock and A. H. Dykes, the contract system of charging (a fixed price per lamp per annum) was recommended for small lighting consumers. For scattered districts, a H.T. A.-C. supply, discontinued during the daylight hours except during periods of fog, was suggested. An earthed-neutral three-wire 50- or 100-volt distributing system with house-transformers for outlying consumers, was recommended. In the discussion, Mr. G. Wilkinson, of Harrogate, stated that, in spite of the fact that about half the lamp connections on his mains were metal filament lamps, his output for the last quarter was only 2 per cent. less than that of the corresponding quarter last year. Several speakers disagreed with the authors' suggestions for a "contract" charge and for a dusk to dawn supply only, many urging the development of a heating and cooking load as a means of increasing the revenue. The cost of services and wiring was also discussed. (Page 1025.)

A PATENT covering a certain construction of miners' electric safety lamp with a magnetic unlocking device expires to-morrow. The patent was taken out in 1895 by Messrs. Ackroyd & Best. (Page 1027.)

IN a new pattern of porcelain ceiling rose, which is illustrated, the wires are simply bared for a short length, slipped under clips, and screwed up, and are not cut. (Page 1028.)

A MODEL electric home has been opened at Catford by the South Metropolitan Electric Light & Power Co., Ltd., to serve as a permanent exhibition of electrical domestic appliances. All lighting, cooking, and heating is carried out electrically, and the house is inhabited, so that all the appliances are in constant practical use. (Page 1028.)

IN a Paper read before the Society of Arts on Wednesday of last week, Mr. T. Thorne Baker described the various systems of transmitting photographs telegraphically, and then demonstrated and explained his own system. He hoped, he said, to develop a system on the same lines for transmitting over very long distances by wireless. (Page 1029.)

AMONG the specifications published by the Patent Office on Thursday was one by the Chloride Electrical Storage Co., Ltd., for an automatic switch for changing over a circuit from a main to an auxiliary source of power on failure of the main supply.—A wiring system especially adapted for temporary work, comprising insulated tubular conductors and jointing pieces with pointed wires to enter the conductors, is covered by A. E. Lamkin and T. R. Nunwick, and a metal trough wiring conduit for thin partition walls is protected by W. W. Strode.—The Adams Manufacturing Co., Ltd., have a worm-operated motor-starter with a quick step-by-step motion. A means of ensuring the substitution of the carbon bye-pass on the burning out of a filament of a Stearn multiple bulb series lamp is also described.—An A.-C. water-heater or geyser on the eddy-current principle is protected by A. Ponzini.—The grant of a patent to G. Michaud and E. Delasson for filaments of refractory oxides has been appealed against. (Page 1030.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, DECEMBER 2ND.

Röntgen Society.

8.15 p.m. At 20 Hanover Square, London. "Some Effects of Electrical Discharges on Photographic Plates," by Prof. A. W. Porter.

FRIDAY, DECEMBER 3RD.

Institution of Civil Engineers: Students' Section.

8 p.m. At 25 Great George Street, London. "The Design of Generating Stations," by G. Ingram.

Faraday House Old Students' Association.

8-11 p.m. Smoking Concert and "At Home," at Faraday House, London.

SATURDAY, DECEMBER 4TH.

Finsbury Technical College Old Students' Association.

6.30 for 7 p.m. Annual Dinner at Criterion Restaurant, London.

TUESDAY, DECEMBER 7TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. At Municipal School of Technology. "The Electrical Equipment of Cranes," by A. L. Hawes.

Institution of Civil Engineers.

8 p.m. At 25 Great George Street, London. "Marine Propulsion by Electric Motors," by H. A. Mavor.

Digitized by Google

WEDNESDAY, DECEMBER 8TH.

Institution of Electrical Engineers.

7 for 7.30 p.m. Annual Dinner at Hotel Cecil, London.

Association of Engineers-in-Charge.

7.30 p.m. At St. Bride Institute, Fleet Street, London. "Recent Developments in Impulse Steam Turbines," by K. Andersson and E. Meden.

THURSDAY, DECEMBER 9TH.

Institution of Electrical Engineers.

8 p.m. At 25 Great George Street, London. "Notes on Methods and Practice in the German Electrical Industry," by L. J. Lepine and A. R. Stelling.

Institution of Electrical Engineers: Dublin Section.

8 p.m. At Royal College of Science. "The Tierney-Malone Point Shifting Device as used on Dublin and other Tramways," by T. P. Tierney.

ELECTRICAL TRADE WITH JAPAN

AS has already been announced in these columns, the exhibition at Shepherd's Bush next year (from May 3rd to the end of October) will be a Japan-British Exhibition. The preparations are being made under the auspices of the Japanese Government, and it is hoped that it will greatly stimulate the trade between the two countries. Japan already buys from Great Britain about £24,000,000 worth of British goods annually, but nevertheless there is an enormous scope for increase, especially in the engineering and allied industries. Japan herself is demonstrating her commercial and intellectual progress as well as her naval and military developments in various sections of the Exhibition, but in the Machinery Hall all the exhibits are to be purely British. For some years past our engineering manufacturers have exported a great deal to Japan, and it is evident that British designs and workmanship are appreciated in that country. The activity in this direction in the electrical industry has, however, been considerably less, and the present Exhibition should afford an exceptional opportunity for electrical manufacturing firms to make the Japanese buyers acquainted with their products.

We understand that a strong committee is being formed for the electrical engineering section, and that Mr. W. M. Mordey (last year's President of the Institution of Electrical Engineers) has accepted the chairmanship, while Dr. Gisbert Kapp (President of the Institution) is to be Vice-Chairman. Distinguished men have also accepted the chairmanships of the other engineering sections; and Messrs. Vickers, Sons & Maxim, Armstrong, Whitworth & Co., and Platt Bros. & Co. are among the large firms who have already decided to exhibit on a large scale. In the electrical section matters are now sufficiently far forward for the Exhibition Committee to invite applications for space from intending exhibitors, and we have no doubt that many firms who are desirous of increasing their export trade will respond.

ELECTRICALLY-DRIVEN REVERSING ROLLING MILLS

THE Paper on electrically-driven reversing rolling-mills, which was read by Mr. C. H. Ablett before the Institution of Engineers and Shipbuilders in Scotland recently (see ELECTRICAL ENGINEERING, November 4th, p. 945), was discussed in Glasgow on Tuesday of last week. In this Paper Mr. Ablett described the working of the Ilgner system with flywheel converter, and gave some particulars of the latest forms of rolling-mill motors with forced ventilation. He explained also the control and safety devices employed. It was mentioned that the flywheel sets could be driven direct by steam turbines, and the use of exhaust-steam turbines for such work was suggested.

The discussion was opened by Mr. A. LAMBERTON (Messrs. Lamberton & Co., Coatbridge), who could not understand how it was possible to reverse and accelerate to 60 revs. 28 times a minute with a 19-ton rotor. He was of opinion that the various devices in the electrical system would require more skilled supervision than did a steam engine, and he did not agree with the author that the capital cost of an exhaust steam turbine plant with Ilgner converter to replace an old engine would be about the same as that of a new steam rolling-mill engine. For continuous rolling mills, driving by electric motor was altogether ideal, and he thought that when electric current could be got cheap enough the steam engine must take a back place. The putting down of gas generators for reversing rolling mills, driving Ilgner sets for storing up energy so as to take the peak loads during the actual pass, and recover its energy between passes, and then installing large motors with reversing apparatus, however, ran into such a tremendous cost that it would appear to put it entirely out of court when compared with simple steam-driven reversing mills. He complained that Mr. Ablett had not given sufficient actual figures of money saved per ton rolled by the adoption of electric driving.

Mr. THOS. MACKENZIE (Messrs. David Colville & Son, Motherwell) had visited the Hildegardehütte Works, and saw the mill there at work. The drive was applied to a bar mill having four stands of housings, the rolls being 29½ in. in diameter. The mill was originally driven by a twin reversing engine of the usual type, the steam pressure being 90 lbs. per sq. in. The electrical equipment consisted of three direct-current motors in series mounted on a shaft connected by intermediate lengths with the mill. These motors had a normal capacity of 3,600 h.p., and a maximum of 10,350 h.p., and were capable of running up to speeds of 120 r.p.m. in either direction. The Ilgner flywheel converter set was driven by a 3,000 volt 50-cycle three-phase motor of 1,500 kw. normal rating. On either side of this was a 26-ton flywheel 13 ft. in diameter, and beyond this again there were two variable voltage 1,500 kw. generators in series. The speed of the converter set was 300 to 375 r.p.m., with a variation of 11 per cent. above or below the mean speed. The cost of the whole equipment was said to be about £20,000. At the time of his visit, flat bottom rails, weighing 90 lbs. per yard, were being rolled from 17 in. square 2-ton ingots; three stands of housings were being used, and 23 passes were given from the ingot to the finished rail, the total elongation being 27/30 fold. Fourteen of these passes were given in the cogging; four in the roughing; and five in the finishing rolls. The mill was working at the rate of 20 tons per hour, but was only operated on the day shift. Tests showed that the variation of input power to the motor driving the flywheel converter was only 3·34 per cent. over, and 6·2 per cent. under the mean. The maximum power taken by the mill was 4,800 h.p., the speed of the mill being 110 r.p.m. As the maximum power reflected back to the station was 1,875 h.p., the flywheels were absorbing peaks amounting to no less than 2,925 h.p. As the mean power reflected back to the power station was 1,050 kw., and the output 20 tons per hour, energy was being absorbed at the rate of 52·5 kw.-hours per ton rolled. The electrical energy was generated in the works by three turbo-alternators. The boilers were fired by waste gas from the blast furnaces, and he had been informed that, allowing for interest on capital expenditure, but charging nothing for the waste gas from the furnaces, energy was being generated for 0·11d. per unit. The cost therefore of electric energy to roll the rails then being made was 5·8d. per ton. Taking £21,000 as the cost of the complete installation, and allowing 10 per cent. for interest and depreciation, the annual capital charge would be £2,100, which, expressed at a rate per ton, gave 4·6d.; which, added to the energy charge of 5·8d., gave 10·4d. per ton as the charge for power, but exclusive of wages of drivers and other attendants. Mr. Mackenzie went on to give some figures comparing the cost of driving a mill which required about 20 brake h.p. hours per ton of steel rolled. The first case was that of a compound condensing reversing engine; the second case was that of an all-electric reversing drive; and the third was an electric reversing drive, but with the motor and the flywheel converter set replaced by a mixed pressure turbine. In the first case, he thought a compound condensing reversing engine, with a barometric jet condenser, electrically driven, hot and cold water, and dry air pumps and cooling tower, would cost about £5,000. Interest and depreciation at 10 per cent. gave a rate per ton for capital charges between the limits of output, varying from 4d. per ton at 30,000 tons per annum output, to 8d. per ton at 15,000 tons per annum output. Taking the steam consumption at 35 lbs. per brake h.p. hour, and with fuel at 6s. per ton, 100 lbs. of steam could be generated for 1d., including boiler plant charges, interest, depreciation, wages, upkeep, &c. The cost of the steam for the main engine was therefore 7d. per ton rolled. To this must be added the cost of driving auxiliaries, bringing up the figure to 8·d. per ton. This might be taken as the cost at the maximum output of the mill, but would increase as the output is reduced, as the rolls will be kept turning round waiting for billets, to, say, 10·2d. per ton at 15,000 tons output. The total cost, therefore, between the limits of output given varies from 12·6d. to 18·2d. per ton. Referring to the all-electric drive, the speaker said that the cost of a flywheel converter set with motor, flywheel, variable voltage generator, mill motor, and all accessories, on the Ilgner system for the plant under consideration, would be about £7,500. With interest and depreciation as before, they would get a capital charge

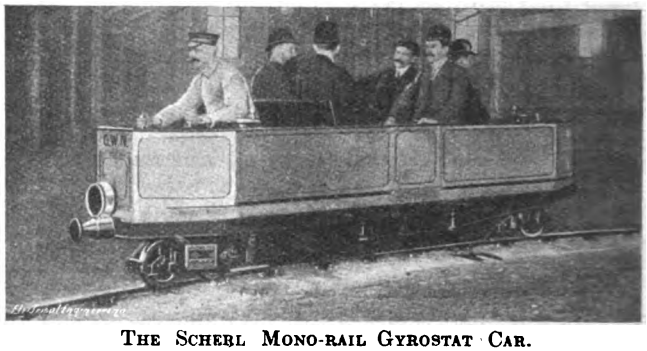
Digitized by Google

varying from 6d. per ton at 30,000 tons output per annum, to 12d. per ton. Taking the over-all efficiency of the drive at 62 per cent., the input to the motor driving the flywheel converter set would be 24 kw.-hours per ton. With current at ¼d. per unit (at which rate it could be produced in fairly large works power stations using exhaust steam turbines working with a load factor which can be had in a steel works), the energy charges worked out at 6d. per ton. This would increase as the output diminished to possibly 6·6d. per ton at the lower limits of output. The sum of the two charges for this case would therefore be 12d. per ton at 30,000 output, increasing to 18·6d. per ton at 15,000 output. It would therefore be seen that with a maximum output assumed, the electrical drive was 0·6d. per ton cheaper than steam; with an output of 20,000 tons they are equal; but at the minimum output assumed, the electrical drive would be dearer than steam by 0·4d. per ton. If, however, by the use of gas engines using cheap power gas, the energy could be got at, say, one-tenth of a penny per unit, the total charges would then be reduced to 8·4d. per ton at the maximum output, increasing to 14·7d. at the minimum. In this case the electric drive would be cheaper than steam throughout the whole range by a figure varying from 3·5d. to 4·2d. per ton. In the third case, the cost would probably work out at about £9,000. The capital charges, taken as before, caried between 7·2d. and 14·4d. per ton. Allowing from 2·6d. to 4·2d per ton as the cost of live steam required in addition to the exhaust steam, the total cost per ton would vary between 9·8d. and 18·6d. As compared with a steam drive, there would be a saving of 2·8d. per ton, decreasing to zero and becoming more costly by 0·4d. per ton at the lower limit of output. The speaker pointed out that the larger the mill the better the case would be for electricity. At Hildegardehütte, it would appear that the capital charge was 1·3d. per ton. The net power to drive the mill was 40 brake h.p. hours per ton. The lowest rate given for steam in Germany was equivalent to 0·011d. per lb. This would bring the cost of steam out to 26·4d. per ton, which, added to the capital charges, gives 27·7d. as the cost of rolling with steam. The cost with electricity was 10·4d. per ton, which was a saving of 17·3d. per ton. This meant that the plant would pay for itself in two years.

Mr. Walter B. Dixon (Messrs. W. Dixon & Co., consulting engineers, Glasgow) said that from three or four years' experience of the Ilgner system, he had proved it to be absolutely reliable, and could effect great economy of power.

Mr. S. A. Simon (of the Electrical Company, Glasgow) emphasised the saving in boiler plant that could be obtained with the Ilgner system. For instance, it had been stated that in cogging ingots of about 19½ sq. in., weighing from 17 to 50 cwt. each, 392 lbs. of steam per ton rolled with an elongation of eight times were required, and 610 lbs. of steam per ton with an elongation of about 17·85 were required. The boiler heating surface required to this steam works out at 8,000 sq. ft. Tests on similar work by electric rolling mills had proved that only 73 to 75 per cent. of this steam consumption was required. Electric tests had shown that for doing similar work about 18 kw.-hours per ton were required for eight times elongation; 26 to 27 kw.-hours per ton with an elongation of 17·85. To put this into lbs. of steam consumed, 17·5 lbs. per kw. might be taken, but with large boilers the steam consumption had been reduced under test conditions to under 13 lbs. The steam consumption corresponding to the figures just mentioned for the electrical rolling plant would be about 315 lbs. of steam, compared with 392 for cogging eight times elongation, and about 475 lbs. of steam as compared with 610 in the case of the steam engine-driven rolling mill when cogging to 17·85 times elongation. Not only is the steam consumption so much less, but owing to the equalising effect of the balancer of the Ilgner set, the heating surface of the boilers could be much smaller, because in the steam engine-driven set the boilers had to be built large enough to take the heavy peaks of load. For the turbines for driving the station just mentioned, about 3,350 sq. ft. heating surface would be sufficient, as compared with the figure given above of 8,000 sq. ft. for steam. Another point which must be considered in the question of the electrification of reversing rolling mills was that of the centralisation of the whole power of the mill.

Mr. R. M. Neilson (consulting engineer, Glasgow), in speaking of the amount of boiler plant necessary, said that account should be taken of the fact that it is often possible to utilise advantageously the exhaust steam from a reciprocating engine, and so obtain power without any addition whatever to the boiler plant.



Mr. G. Ness (Scottish Boiler Insurance Co.) mentioned the case of an Ilgner set erected for winding shale, in which the economy had not come up to anticipations owing to the conditions in mines not allowing trips to be made at short intervals. In the same way, the efficiency of the system which Mr. Ablett had described would depend, he thought, very largely on the regularity with which the ingots could be kept running. No doubt the great stumbling-block of the system was the capital outlay, as where one could get 20 mill-owners to expend £5,000, hardly one could be got to expend £25,000.

Mr. Ablett, in his reply, remarked that since the beginning of this year seven firms of steel makers on the Continent had decided to adopt this method, which, he thought, showed that there must be economy in it. He did not set very much value on calculated figures of costs, because there are so many points which are open to question, and very often the difficulty is met with that when people are making an economy they want to keep quiet about it. It would be very valuable, Mr. Ablett said, if comparative tests could be made on a steam mill and an electrically-driven mill rolling similar material under similar conditions. He was prepared to carry out such tests with an electrically-driven reversing mill, and publish figures if Mr. Lamberton would do the same with a similar type of steam-driven mill. In reply to Mr. Lamberton's remarks as to speed of reversal, at a test it was found possible, in the particular mill, to reverse from full speed in one direction to full speed in the other in 1½ seconds. With regard to the question of the capital cost of the mill engine, and the plant driven by an exhaust steam turbine, he could speak with some authority about the electric plant, and say that the cost mentioned by Mr. Lamberton of £25,000 is a great deal too high. Mr. Ablett was quite in agreement with Mr. Mackenzie that the ideal case for an electrically-driven reversing rolling mill was a big mill with a big output, because the capital cost is always more than that of the steam engine, and the saving per ton has to out-balance the capital charges on the extra capital cost.

THE SCHERL MONO-RAIL GYROSTAT CAR

A RECENT issue of our German contemporary, *Elektrische Kraftbetriebe u. Bahnen*, contains a description of the Scherl mono-rail gyrostat car, the exhibition of which in Berlin was the cause of Mr. Brennan's hurried demonstration a short time ago of his new full-size vehicle (see Electrical Engineering, November 18th, p. 977).

The Scherl car, illustrated in the accompanying figure, measures nearly 20 ft. over the buffers, and has a maximum width of nearly 4 ft. It carries six persons, including the driver, and has a dead load of approximately three tons. As in the Brennan design, there are two 2-axle bogies, the distance between the bogie centres being about 15 ft. Each wheel has a diameter of about 16 in., and a groove radius of 1·2 in. The car was shown running in the Exhibition Hall at the Zoological Gardens, Berlin, on an oval track, with a total length of about 160 yards. This consisted of a 20 lbs.-per-yard rail, with a rounded head just over an inch wide. This rail was supported on wood sleepers 2·5 ft. apart, laid on a cement floor. The minimum radius of curvature of the track was 25 ft. One wheel of each bogie is driven through double-reduction gearing by a 2 h.p. continuous-current motor supplied

The Scherl Mono-rail Gyrostat Car.

with current at 110 volts from two 7 mm. diam. copper conductors supported on porcelain insulators, one on each side of the rail. Small contact shoes are attached to the bogies. Two controllers, one at each end of the car, enable it to be driven from each extremity. The stability mechanism comprises two gyrostats rotating in opposite directions. Each gyrostat consists of a 110-lb. wheel of special cast steel rotating at 7,000 r.p.m. in an air-tight chamber, the pressure in which has been reduced practically to zero. Each wheel is direct-coupled to a ½ h.p. 110 volt shunt motor. The precession is artificially accelerated to obtain the balancing effort by means of an apparatus operated by oil under pressure.

The writer of the article in our German contemporary, Herr Eugen Eichel, asserts that when standing still the car oscillated somewhat from side to side; otherwise it appears to have behaved well, to have balanced itself when the load was shifted, and to have inclined inwards on taking curves. Although it is estimated that the car will attain a speed of 19 miles per hour on a straight run, it was run at a speed of only six miles per hour on the oval track. It is stated, however, that thorough tests will shortly be made in the railway test yards at Dresden, which will be followed by the construction of a full-size vehicle.

ACCIDENT THROUGH HIGH-FREQUENCY TREATMENT

An interesting case was heard before Mr. Justice Channell and a jury last week. A Miss M. J. Stephens recovered damages from the Dowsing Radiant Heat Co., Ltd., for injuries she had sustained during high-frequency treatment at their establishment. She had been recommended by her doctor to have electric baths, but on calling at the Dowsing Co.'s establishment, they suggested that high-frequency treatment would be more suitable for her case. The doctor consented to the treatment, which was carried out with the usual apparatus. In this the patient reclines on a couch, underneath which is a sheet of metal connected with one pole of the high-frequency apparatus, and the other pole is connected to handles which the patient holds. During the treatment she complained that she experienced burning on one of her legs, but the nurse continued the treatment. On Miss Stephens moving she had the same burning sensation on her other leg. When she reached home she found that she had been seriously burned in both places. Acute dermatitis supervened, and she was confined to bed for three weeks.

Subsequently, Dr. Lewis Jones (medical officer in charge of the electrical department at St. Bartholomew's Hospital) was consulted, and found that the dress she was wearing was trimmed with tinsel braid containing a certain amount of metal. It was where this metal had touched her legs that the burning took place. Dr. Lewis Jones's theory was that a wire had probably been in contact with this braid, or else the braid had been in contact with earth, and that thick white sparks, which would burn very rapidly, had thus been discharged between the braiding and the patient's leg, passing through her stocking and inflicting the burns complained of. Only a few seconds would have sufficed for this. For the defence it was contended that there could have been no earth or wire in contact with the braid, and that there had been no negligence in the treatment. The jury found otherwise, however, and returned a verdict for the plaintiff with £60 damages.

This case emphasises the extreme care that should be taken in applying the high-frequency treatment. No pain at all should be experienced, and, immediately on a patient complaining, it is a sign that sparking is occurring somewhere. Nurses administering the treatment should be instructed to turn off the current immediately a patient complains of pain; but as high-frequency apparatus requires technical knowledge for its proper understanding, it would be better still if it were only applied by a medical man having a knowledge of electricity. Cases of sparking have occurred before in connection with dresses with metal braiding, and with heavy patients it is not unknown that a spark will pass from the plate beneath, right through the mattress which acts as dielectric, penetrating the clothes, and reaching the under side of the patient's body. As we have said before, no harm is done in such cases if the current is immediately switched off.

THE PARLIAMENTARY SESSION OF 1910

We give below particulars of further Bills of electrical interest which will be promoted in the next session of Parliament.

The incorporation of the Wimbledon & Sutton Railway Co. is proposed, for the construction of an electric railway between Wimbledon and Sutton.

Mersey Railway Co. seek an extension of time with respect to the payment of interest on certain debenture stocks, and other matters.

Alteration and amendment of the Widnes Electric Lighting Orders of 1901 and 1904 will be applied for by the Council.

Yorkshire Electric Power Co. propose to amend their financial powers.

Further powers in respect of their electric lighting undertaking will be applied for by the Handsworth District Council.

The incorporation of the Bishops Stortford, Harlow, and Epping Gas & Electricity Co. will be applied for.

Middleton and Warrington Corporations will apply for wiring powers, &c.

New tramways are proposed by the Rawtenstall Corporation, and the Milnrow District Council.

The incorporation of the Chipping Norton Gas and Electricity Co. is proposed. An Electric Lighting Provisional Order for Brixham will be applied for by R. A. Lister & Co.

An order will also be applied for for Gorseinon by the Gorseinon Electric Light Co., Ltd. Amendment of the Dawlish Electric Lighting Order is proposed.

Extensions of the Halesowen Light Railways will be sought.

Accident to Mr. E. Kilburn Scott.—We regret to hear that Mr. E. Kilburn Scott was knocked down by a motor-cab in the Strand on Monday. The accident occurred through Mr. Scott slipping whilst crossing the road, and the vehicle passed over him, fracturing his leg. It was feared that he had also suffered internal injuries, but on Tuesday he was progressing favourably at King's College Hospital, and the injuries have turned out to be not so serious as were at first anticipated.

CORRESPONDENCE

ELECTRICAL DRIVING OF TEXTILE FACTORIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—As members of the Special Committee of the Bradford Engineering Society appointed to consider the electrical driving of textile factories, we desire to protest against the recently published document described as a report of the Committee. [ELECTRICAL ENGINEERING, October 21st, p. 909.]

Several portions of this document have been published without our knowledge or approval, and without an opportunity being given to the Committee as a whole to discuss it. It does not represent the views of the Committee, and is in many respects misleading.

The impression that this document gives, viz., of being the outcome of careful inquiries and exhaustive tests, is erroneous; it represents the results of preliminary discussion among the members of the Committee and of two tests which were by no means exhaustive.

We therefore desire to disassociate ourselves from it.

Yours, &c.,

H. ELLIS, H. A. JONES, R. POHL, T. ROLES,
C. W. SALT, W. B. WOODHOUSE.

Bradford, November 30th, 1909.

ARC LAMP PATENT ACTION IN GERMANY

On November 22nd, the German Patent Office revoked the German Patent No. 186,758, owned by the Deutsche Beck-Bogenlampen-Gesellschaft. The Regina Bogenlampen Fabrik, of Cologne, to whom we are indebted for this information, had placed a flame arc-lamp on the market under the name of the "Conta" lamp, in which the tip of the negative carbon rested on a support at the base of the lamp, there being no clockwork feeding gear. The Beck Co. alleged that this lamp infringed their patent, which, they claimed, covered this method of supporting the carbons. As a reply to this, the Regina Co. applied for the revocation of the patent (apparently on the ground of anticipation), and were successful.

In the "Conta" lamp, which can be used on either A.-C. or D.-C. circuits, the negative carbon is perpendicular, and the inclined positive carbon is swung for striking and regulating by means of a sliding collar on the base-plate, actuated by a series solenoid. The holders of the two carbons are mechanically connected and feed down as the carbons are consumed, the tip of the negative carbon resting on a swinging support under the base-plate. This support has an extension upwards, which presses against the negative carbon some few inches above the point. It is so pivoted, that when the pressure of the carbon on the lower part is released, the upper extension swings away from the carbon and allows it to descend until it again touches the lower part. By supporting the carbon from the side in this way, the breakage of the point is avoided. As the arc is some 5 mm. distant from the support, the latter does not require frequent renewal. These lamps are stated to run well in series with very even distribution of pressure across the arcs. The Regina Co. has also brought out a "Conta" lamp with an inner prismatic globe, which, being close to the arc and well swept by the air currents, remains free from deposit.

TURBO-ALTERNATORS FOR SYDNEY

In our issue for Sept. 9th we mentioned that the Sydney Corporation had, against the advice of their resident engineer, decided to advertise for tenders for two 4,000-kw. turbo-alternators running at 1,500 r.p.m. The resident engineer, Mr. Forbes Mackay, had previously recommended the acceptance of a tender for machines running at 750 r.p.m., and pointed out that the balance of experience was in favour of the slower speed.

We now understand that the final selection has fallen on Willans & Robinson turbines, and on Dick, Kerr alternators. Two units of 4,000 kw. each, running at 750 r.p.m., are to be installed. Thus the Council has adopted the wise course of following the advice of their engineer. The prices originally submitted, but which included a 400-kw. unit in addition to the two 4,000-kw. units, were as follows:—British Thomson-Houston turbines, £32,354; British Westinghouse turbines, £34,007; Oerlikon turbines, £35,887; Willans & Robinson turbines, £40,690; Escher Wyss turbines, £42,175; Willans and Dick, Kerr sets (accepted), £44,547.

Arc Lamp Carbons for the Admiralty.—In reply to a question in the House of Commons last week, Mr. McKenna stated it was not true that the Admiralty placed their orders for arc lamp carbons with foreign firms. The whole of the supply was obtained from Great Britain.

HYDRAULIC STORAGE FOR ELECTRIC GENERATING STATIONS

SUGGESTIONS have been made for the improvement of the load factor of the steam plant in generating stations, which consisted in employing the engines to pump water into high-level reservoirs or into tanks under air pressure, in periods of low load, and using the water to run turbine-driven sets assisting the steam plant during the peak-load period. The heavy capital cost of such an arrangement has prevented the idea from being realised in practice, but a similar suggestion was made by Mr. H. A. Humphrey in a Paper read before the Institution of Mechanical Engineers on Nov. 19th. In this Paper Mr. Humphrey describes his internal-combustion pump, in which a combustible gas mixture is exploded directly over water which is forced out of the apparatus and discharged into a high-level tank. The kinetic energy of the out-flowing water is utilised to draw more water into the combustion chamber and to exhaust the burnt gases, and the pressure due to the water in the high-level tank is employed subsequently to compress the fresh charge of gas before ignition. The theory of this apparatus, its construction, and the results of many tests are given in the Paper, and the author then describes some of its applications. After dealing with its use as a high-lift pump and as an air-compressor, the author suggests that such internal combustion pumps might be substituted for gas engines in electric power stations. Water would be pumped into large air vessels and fed from these to water turbines driving the generators. The turbines would discharge into a common tank, from which the pumps would be supplied. Gas for working the pumps would be generated in a suitable producer plant. Any one or more of the pumps could be started from the switch gallery at a moment's notice, or an automatic gear could be arranged so that the pressure in the air vessels would be kept constant. Mr. Humphrey estimates that a small plant would generate one kilowatt-hour for every two pounds of anthracite coal consumed, on the assumption of a turbine efficiency of 80 per cent. If the contour of the surrounding district permitted, a high-level reservoir could be constructed and the pumps could work on a 100 per cent. load factor, and only the turbines and generators would have to be of a size sufficient to supply the maximum load.

WIRELESS TELEGRAPH NOTES

Mr. G. Marconi and Marconi's Wireless Telegraph Co., Ltd., are applying for an extension of the life of the original Marconi wireless telegraph patent No. 12,039 of 1896, which in the ordinary course would expire on June 2nd next. Notices of opposition to the extension must be lodged in the Chancery Division of the High Court before January 14th next.

Representations are being made to the Indian Government to include Dacca in the scheme under which wireless telegraph stations are to be established in India. It is pointed out that the storms in this district invariably wreck the telegraph lines in Eastern Bengal, cutting the province off from communication with India altogether. The distance between Calcutta and Dacca is 170 miles, and it is claimed that there should be no difficulty in establishing wireless communication between the two places.

A vote of £10,000 for the erection of a wireless telegraph station near Cape Town has been sanctioned by the Legislative Assembly.

On consideration of the Expiring Laws Continuance Bill in the House of Commons on Wednesday of last week, Mr. Hay moved the omission of the Wireless Telegraph Act of 1904 from the list of measures extended by the Bill. His reason was to ask if the Postmaster-General had entered into certain contracts with the Marconi Wireless Telegraph Company under the Wireless Telegraph Act, and had spent £15.000 in acquiring certain rights of the company which, he believed, were not worth anything, inasmuch as the company had been allowed to retain the two long-distance stations at Clifden and Poldhu. The Postmaster-General replied that the Wireless Telegraph Act was included in the Expiring Laws Continuance Bill this year for the reason that no necessity was felt for altering the Act. In view of the operation of the Radiotelegraphic Convention and the purchase of the Marconi and Lloyd's stations, it was possible that a more comprehensive wireless telegraph Bill would have to be introduced in a few years' time. With regard to the terms upon which the Marconi stations had been purchased, in view of what took place in connection with the telegraph companies, and what had yet to take place in relation to telephones, he was convinced that the Government had made a very good bargain, especially as they had obtained the use of all the Marconi patents.

The Australian Postmaster-General, Sir John Quick, has issued a statement dealing with the intentions of the Government in regard to erecting wireless telegraph stations at Sydney and Fremantle. Some delay has arisen in connection with receiving the advice and assistance of Vice-Admiral Sir Richard Poore. In the opinion of this officer, the two stations in question should be capable of maintaining communication over a distance of 750 or 1,000 miles, and he recommends the adoption of the Marconi system. This latter recommendation is not consistent with the advice of Vice-Admiral Poore's predecessor, and in view of the apparently conflicting advice, the Postmaster-General has communicated with Captain Muirhead Collins, the Australian Government representative in London, and has asked him to obtain expert advice as to whether tenders should be restricted to the Marconi system.

A Central News cable from Cape Town states that a representative of the Marconi Co. has had an interview with General Smuts with regard to the establishment of a wireless telegraph system in the Transvaal. The company offers to erect a station at Johannesburg, and to establish a "shilling a word" system in competition with the present half-a-crown rate of the cable companies.

ALUMINIUM SOLDER

A PRESS demonstration of an aluminium solder was given on Tuesday by the Aluminium Patent Non-Flux Solder, Ltd. (10 Camomile Street, E.C.). The process is not new, having been tried many years ago with success, although it has only just been patented and put on the market.

The majority of fluxes contain a chloride, and, owing to the harmful effect of chlorides on aluminium, the advantage of a solder requiring no flux is at once apparent. It was discovered that a certain soft rare metal (when raised to a certain temperature) had the same effect on an aluminium surface as a flux on most other metal surfaces, and the present solder consists of an alloy of this metal with several others to give it the necessary hardness. Owing to the high price of the rare metal, the cost of the solder is as much as 17s. 6d. per lb., but only a very small quantity is necessary in most cases, as an aluminium surface "tinned" with this material will take any ordinary solder. The surface is first scraped so as to remove the film of oxide, and the solder applied with a steel bit at the usual temperature. Aluminium can be soldered to aluminium or any other metal with this solder. Many very satisfactory tests have been made. Some blow-holes in an aluminium casting were filled up, and when the casting was turned the solder remained intact. A strip cut in two, and then dovetailed and soldered, broke at the normal breaking stress of 3,300 lbs. per sq. in., and then not at the joint. Further, a strip, soldered in the centre, was rolled under pressure, and there was no indication of the joint having "started," thus establishing the ductility of the solder. When soldering aluminium to other metals it is only necessary to first "tin" the aluminium surface with the new solder, and then work with ordinary solder and flux. No figures are as yet available as to the conductivity of the solder. For filling up cracks in castings and other similar work, a cheaper quality solder is used.

The New King's Dock at Swansea.—Although the greater part of the appliances in connection with the new King's Dock opened last week at Swansea is driven hydraulically, there will also be a large electrical plant for lighting and power purposes. The generating plant will consist of Willans-Peebles 3,000-volt three-phase turbo-alternators and Lancashire type boilers, with superheater, economiser, &c., and will be installed by Messrs. H. & T. Danks. Motors over 50 h.p. will be run direct off the 3,000-volt circuit, and small three-phase motors will be worked at 460 volts. A 250-volt continuous-current supply will also be given from motor-generator sub-stations equipped by Messrs. Crompton & Co. The quays, sheds, warehouses, &c., will be lighted by arc and incandescent lamps, and electric cranes are being installed in the sheds for transhipping goods. Electric cranes are also to be installed on the quays. An electric transporter will be used for the transhipment of pitprops, iron ore, &c., direct from the ships to the unloading ground.

The Eight Hours' Bill and Electrical Haulage.—In view of the serious effect which the shortening of working hours in mines is likely to have on costs of production, the question arises of improvement of the position by the increased adoption of mechanical methods of haulage and alteration to pumping plant. This is pointed out in a booklet which is being issued by Messrs. Ernest Scott & Mountain, Ltd. (Close Works, Gateshead-on-Tyne), who further remark that the greatest difficulty will undoubtedly arise in getting the coal from the working face to the main haulages, work which has hitherto been done either by lads and men alone, or with the assistance of horses or ponies. As there has been in the past nothing to prevent the hours for these men being longer than those worked by the hewers, it has always been possible to make sure that the whole of the coal obtained at the face in the one or two shifts reached the surface within the time available. In the future, owing to the reduction of all time underground to a maximum of eight hours, with intervals of not less than sixteen hours between shifts, colliery managers will be compelled to adopt methods of transport which will get the coal away from the face as rapidly as it can possibly be won by the hewers. The booklet explains the various systems of electric haulage, suitable for different circumstances, by the aid of diagrams, and gives numerous excellent illustrations of both main rope, main and tail, and endless rope gears, also portable gears which have been designed to dispense with horses underground. Useful tables are also given for calculating the powers for haulage.

LOCAL NOTES

ABERDEEN: *Corporation and Tramways Company.*—The Corporation have decided to take counsel's opinion as to the manner in which the award of Mr. W. H. Patchell, the arbitrator, concerning the price to be paid by the Aberdeen Suburban Tramways Co. for electric energy, shall be enforced.

Electric Power at the Harbour.—A special article in the *Aberdeen Evening Express* last week points out that during the past twelve years very considerable changes have been made in the methods of working the docks at Aberdeen. Electricity has practically entirely displaced steam power, all lighting, heating, lifting, &c., being performed electrically. Current is taken from the Corporation mains, and the cost of the electrical work, apart from the supply of electrical energy, has been about £15,000.

AUSTRALIA: *Electric Supply in Melbourne.*—A short time ago, says the *Australian Mining Standard*, the South Melbourne City Council convened a conference of suburban municipalities to consider a proposal to jointly employ an expert at a fee of £750 to devise a scheme for electrically lighting such suburbs as are not already supplied. Whilst the proposal was under consideration, however, the South Melbourne Council committed themselves for a further period of seven years to the gas company for street lighting, and, in consequence, the other councils have declined to proceed further with the proposition to hold a conference to jointly discuss electric lighting.

Sydney: Street Lighting.—The Council's electrical engineer has reported that from experiments with metallic filament lamps he is of the opinion that they would not be suitable for lighting the main thoroughfares, except at a considerably greater expense than with arc lamps. He recommends that in the main thoroughfares the existing open arc lamps should be substituted by flame arc lamps, but that in side streets metal filament lamps should be used.

Electrification of Victorian Railways.—In the Legislative Council of Victoria last month, says the *Australian Mining Standard*, the proposal to convert the Melbourne suburban railways to electric traction was raised. The Hon. D. Melville pointed out that the matter appeared to be hanging fire owing to a difference of opinion between the Railway Commissioners and Mr. C. H. Merz. As far back as 1898 a Select Committee had reported that electric traction was rapidly coming into favour all over the world, and recommended that it should be given a trial on the St. Kilda and Port Melbourne lines. A later Committee had reported to a similar effect, and since that date Mr. Merz's report had been prepared, also in favour of electric traction. After some discussion, the Hon. J. Drysdale Brown, on behalf of the Government, stated that the matter was to be gone thoroughly into, and Parliament would be asked to take some action, but as this would mean the borrowing of a large sum of money and the session was far advanced, it was utterly impossible for the Government to do anything this year.

BELFAST: *Proposed Tramway Extensions.*—Mr. Andrew Nance, the tramway manager, has presented a report, in which he recommends the construction of additional tramways at an estimated cost of about £500,000. It is, of course, too late for depositing an appeal in the present session of Parliament, and the matter is to be further considered in March next.

BLACKPOOL: *Tramway Receipts.*—From April 1st to date the receipts from the Corporation tramways exceed those for the corresponding period of last year by more than £4,000. About half of the increase is due to the Blackpool flying meeting.

BRIGHTON: *Supply to Small Consumers.*—The Electricity Committee propose a scheme whereby a consumer, on agreement to pay 1d. per unit above the ordinary rates, may have his premises wired and fitted free of charge.

CANADA: *Tube Railways.*—The Toronto Corporation have under consideration the construction of a system of tube railways.

Electric Traction on Main Lines.—It is reported that the electrification of the Grand Trunk Pacific Railway from the St. Lawrence River to Monckton, a distance of about 460 miles, is under the consideration of the Railway Company, the Canadian Government, and the New Brunswick Cabinet.

CARDIFF: *Supply to Bute Docks.*—Provided an arrangement can be come to for the supply of water as well as electricity to Bute Docks, the Docks authorities are willing to negotiate with the Corporation. The Electricity Committee have asked the Waterworks Committee of the Corporation to appoint representatives with a view to forming a joint committee to negotiate with Sir William Thomas Lewis in the manner suggested.

EAST BARNET: *Provisional Order Revoked.*—The Board of Trade have revoked the Electric Lighting Order granted to the East Barnet Valley Council in 1906.

EDINBURGH: *Proposed Tramways.*—A second scheme has been placed before the Corporation for the construction of tramways to Queensferry. The Corporation had a similar proposal before it a short time ago from another set of promoters, and the two schemes are now under consideration.

GLASGOW: *Smoke Elimination.*—It has been decided to appoint a special committee, consisting of six members each from the Gas and Electricity Committees, and three members from the sub-committee on Air Purification, to make arrangements for holding an exhibition to demonstrate the most up-to-date appliances for the utilisation of electricity and gas for heating and cooking purposes. The object of this demonstration is to urge upon the public the necessity for using such appliances in the interests of the purification of the atmosphere of the city.

The Telephone Service.—In view of the acquisition by the Government of the National Telephone Co.'s undertaking in 1912, it has been arranged that each telephone district in Glasgow shall in the meantime be served by a single exchange, either of the Post Office or the National Co., and the subscribers' lines of both systems in that district are to be connected with the one exchange. For the present, the service will be given by the Company's operators on behalf of the Post Office, but the Postmaster-General will be responsible to the subscribers for the service.

HASLINGDEN: *Electric Supply.*—The Council's provisional order expired on Nov. 25th, and the Board of Trade have intimated their intention not to renew it unless the Council can show that efforts are being made to put the order into force. A canvass of the inhabitants is to be made in this connection.

HULL: *Theft of Electric Cable.*—Two men, named W. Beckett and A. Clark, were fined £5 each and costs, or 30 days' imprisonment at the Hull Police Court on Thursday, for stealing 1 cwt. of old electric lighting cable belonging to the Corporation.

ILFORD: *Electrical Extensions.*—Extensions of the electricity works and tramway-car sheds were opened on Saturday.

LONDON: *Hampstead: Electric Heating and Cooking.*—With a view to encouraging the use of electricity for heating and power purposes in private houses, the Lighting Committee has been authorised to enter into agreements with occupiers on a basis of £8 5s. per kw. per annum (payable in advance), for the maximum demand required for lighting houses throughout with electric light, together with 1d. per unit for all current supplied for whatever purpose it may be required.

Marylebone: Supply of Heating Apparatus.—In order to push the sale of apparatus giving a 100 per cent. load factor, the Council has approved of a tariff of 1d. per unit on same. The general manager of the electricity undertaking has been authorised by his committee to expend £60 during the ensuing year upon literature produced by the Associated Municipal Electrical Engineers (Greater London) through their Publicity Committee.

NEWCASTLE: *Tramwaymen's Grievances.*—In connection with the dispute between the Corporation and the tramway employees, the Local Government Board have suggested that a conciliation board should be adopted similar to that established by the London County Council, and referred to in our last issue. The Tramways Committee, however, have decided not to adopt the suggestion, as they consider the grievances are not of such a serious nature as to render this necessary.

RUSSIA: *Electric Railway.*—According to the *Financier and Bullionist*, the preliminary survey of the projected electric railway between St. Petersburg and Imatra is almost completed. It is said that the necessary deposit has been paid into the Imperial Bank, and that funds for the construction of the lines are assured. Utilisation will be made of the Vuocks River Falls for generating electrical energy in connection with the railway.

Electric Supply and Tramways.—A special correspondent of the *Financial News* at St. Petersburg points out the limited use which is made of electricity in Russia. It is stated that there are only eighty cities lighted by electricity, and thirty possessing electric tramway systems.

SUNDERLAND: *Tramway Service.*—At the annual meeting of the Tramways Committee last week the Chairman stated that the half-year to September 30th had not been a very successful one, the traffic receipts having shown a net decrease of £1,100. There had, however, been a saving of £1,468 in expenditure.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ABERDARE.—The Local Government Board have sanctioned a loan of £17,000 for the installation of an electricity works and for street lighting.

ASTON.—Extensions of mains are to be carried out at an estimated cost of £825.

BRIDLINGTON.—The Local Government Board have sanctioned a loan of £5,057 for electrical extensions. Tenders are

Digitized by Google

to be invited alternatively for a 300-kw. reciprocating set and a 300-kw. mixed pressure turbo-alternator.

DENMARK.—It is announced that negotiations are in progress between English financiers and electrical manufacturers on the one hand, and a number of towns in Denmark on the other, with a view to the installation of an extensive electric supply scheme. A total expenditure of £400,000 is contemplated, which includes about £200,000 upon the construction of an electric railway between the towns of Aarhus and Randers. A number of generating stations will also be erected.

DUBLIN.—The L.G.B. has sanctioned a loan of £75,000 for electrical extensions.

ECCLES.—Mains are to be extended at an estimated cost of £200.

EDINBURGH.—Sir Alexander Kennedy, the Corporation's consulting engineer, has presented a report upon the future working of the Dewar Place and M'Donald Road generating stations, with special reference to cooling towers. The report, which has been printed and circulated among the members of the Corporation, estimates that by installing two exhaust turbines at Dewar Place for three of the present machines, there will be an increase of 3,500,000 units per annum without any increase in the cost of coal and water, if cooling towers were installed. The estimated cost of the proposal is £45,000.

LONDON: *St. Pancras.*—The Highways Committee of the L.C.C. recommend a loan of £5,098 for electrical extensions.

Stepney.—Tenders are to be invited for a complete system of coal and ash-handling plant at Blyth Wharf station.

WALSALL.—A Local Government Board inquiry was held on Tuesday concerning a loan of £35,000 for electrical extensions.

WOLVERHAMPTON.—A Local Government Board inquiry was held last week concerning a loan of £10,000 for electrical extensions. Mr. C. E. C. Shawfield, the Borough Electrical Engineer, told the Inspector that the charges in Wolverhampton for power were the lowest in the country, and that the profit per unit was only 1 ½d. In his opinion, there were very few electrical companies in a sounder condition than the Corporation's undertaking.

Miscellaneous

AUSTRALIA.—Melbourne Council invite tenders by 15th inst. for the supply of 50,750 incandescent lamps. The Council also require 1,800 yards of 0·75 sq. in. single conductor lead-covered cable. Particulars, &c., in both instances from Messrs. McIlwraith, McEarcharn & Co., Ppty., Ltd., Billiter Square Buildings, London, E.C.

Tenders are invited by March 16th, 1910, by the Melbourne Deputy Postmaster-General for a branching multiple magneto switchboard at the Canterbury (Victoria) Post Office.

BURNLEY.—The Council have decided to fit a number of open covered top deck cars with covered roofs, at an estimated cost of £221 per car.

DOVER.—It is announced that capital has been obtained for the construction of a tramway from New Bridge to Eastcliffe.

HARROGATE.—The trustees of Trinity Wesleyan Church invite tenders for the supply and fixing of an electrical blowing apparatus for the organ. Particulars from the Secretary.

LONDON: *London County Council.*—Tenders are invited for the supply of overhead electrical equipments for the construction on the four-wire system of electric traction of tramways from Woolwich to Eltham (see an advertisement in this issue).

Poplar.—The Guardians require an electric fan and fittings at the Workhouse Laundry, High Street. Particulars from the Clerk, 45 Upper North Street, Poplar, and tenders by December 8th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

S.E.—Business premises, Blackfriars Road. Builders, Fairhead & Co., Enfield, N.

E.—Conversion of pupil teachers' centre and education offices into higher elementary school, East Ham. Architect, R. L. Curtis, 50 West Hill, Hornsey, N.

E.C.—Rebuilding premises for Union Bank of Scotland, Cornhill, E.C. Builders, G. Trollope & Son, Halkins Street, S.W., and Colls & Son, Ltd., 5 Coleman Street, E.C.

N.W.—First block of large factory in Hendon for Carl Zeiss & Co., optical instrument makers, 29 Margaret Street, E.C.

N.—Pavilion and rink, Stroud Green Road, Finsbury Park, N. Architects, Fair, Myer & Marshall, 39 Furnival Street, E.C.

N.E.—Skating rink, Lower Clapton Road, Hackney, N.E. Architects, Fair & Myer, 39 Furnival Street, E.C.

PROVINCES.

ABERDEEN.—Rescue Home (£2,000). Architects, Kelly & Nicol, 367 Union Street, Aberdeen.

ACTON.—School (£10,000). Secretary, Acton Education Committee.

BRIGHOUSE.—Salvation Hall (£2,000). Architect, A. Gordon, 95 Queen Victoria Street, E.C.

BURSLEM.—Rink (£2,000). Architect, E. T. Watkin, Swan Bank, Burslem.

CREWE.—Police Station (£3,000). Architect, H. Beswick, Newgate Street, Chester.

ECCLES.—Skating Rink, Corporation Road. Eccles Roller Rink Co., Ltd.

Tenders are to be invited for the electric lighting of the Beech Street Schools.

EDINBURGH.—Masonic Temple (£10,000). Architect, W. A. Carter, 14 Queen Street, Edinburgh.

Tenders are invited for electric lighting and fitting of the various rooms at the new slaughter house, Gorgie. Particulars from the Electrical Engineer, Dewar Place, and tenders by December 6th.

GLASGOW.—Rink, Summerfield Street (£3,000). Architect, J. Lindsey, 248 West George Street, Glasgow.

MANCHESTER.—Tenders are invited for the wiring and fitting of the Harpurhey Baths. There will be about 700 lights. Particulars from the City Architect, and tenders to the Town Clerk by Dec. 13th.

TIPPERARY.—The Board of Guardians having projected a movement for the lighting of the Workhouse by electricity, Mr. L. J. Lawless, Dublin, is the Consulting Engineer.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Sydney Corporation have accepted a tender by Messrs. Willans & Robinson for two 4,000 kw. turbo-alternators and a 400 kw. set at £44,547.

BECKENHAM.—The makers of the battery at the generating station have, in consequence of the reduction of the tramway load, agreed to maintain it at two-thirds of its capacity for £100 per annum for ten years. If the full capacity is subsequently required the cost will be increased to the price now paid, viz., £135 per annum, plus 4 per cent. on the difference between the two sums, but the Council has the option of terminating the agreement or requiring the capacity of the battery to be increased on giving six months' notice, expiring at the end of any contract year.

LONDON: *London County Council.*—A contract for the road-work and platelaying in connection with an extension of the Lea Bridge Road tramways, and also with the junction lines between Lea Bridge Road and Lower Clapton Road, has been placed with Messrs. Dick, Kerr & Co., Ltd.

Marylebone.—The Council have accepted the following tenders:—Lea Recorder Co., one Lea recorder, £70; Crompton & Co., one direct-current converter, £195.

PLYMOUTH.—The contracts for the maintenance of the Tudor batteries at the Prince Rock Works expire this year, and the contract for the battery at the Armada Street sub-station will expire in 1911. The Corporation have accepted an offer by the makers to cancel the contract for the Armada Street sub-station, and to enter into fresh contracts for the maintenance of the batteries at both stations for a period of ten years for £280 per annum.

ST. AUSTELL.—The tender of the St. Austell & District Electric Lighting & Power Co. has been accepted for street lighting at £179 per annum. The tender of the local gas company was £269 per annum.

TORONTO.—The following contracts have been awarded for eighteen electrically driven pumps in connection with the waterworks extensions:—Section A: Jens Orten-Böving, London, $14,800, four pumps with a capacity of 13,500,000 gallons each. Section B: John McDougall, Caledonian Iron Works, Montreal, $11,703, two pumps with a capacity of 5,000,000 gallons. Section C; Jens Orten-Boving, $6,500, four pumps with a capacity of 16,000,000 gallons each. Section D: John McDougall, Caledonian Iron Works, $7,385, four pumps with a capacity of 6,500,000 gallons each. Section E: Canadian General Electric Co., $4,822, four pumps with a capacity of 1,500,000 gallons each.

Recent contracts carried out by the London Electric Firm for their patent "One Working Part" arc lamp lowering gear are:—87 for the St. Marylebone Borough Council, consisting of single and double swan necks and centre carrier gears, for Oxford Street and Upper Regent Street; 72 for the Ealing Corporation, consisting of swan necks and centre carriers on traction pillars, and on lamp pillars with tank transformer bases; 80 for the Swansea Corporation, comprising swan necks, trolley arms, and span wire gears. The centre-pole gears are "converted lyres."

Paris Electricians and the King of Portugal.—The *Daily Telegraph* on Wednesday gave an amusing account of another exploit by M. Pataud, who is head of the Paris electricians trade union. He ordered the electricians at the Opera to leave work just at the moment that the King of Portugal arrived. Under the threat of having no light the management agreed to the terms of M. Pataud that the stage electricians should receive three francs for the performance, the same as the stage hands are paid, despite the fact that the electrical men are not in the employ of the theatre management.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 10s. to £61 10s. per ton (last week, £61 5s. to £61 10s.).

BANKRUPTCIES, LIQUIDATIONS, WINDINGS-UP, &c.—The Adams-Randall Telephone Patents Co., Ltd., is to be wound up voluntarily. Mr. W. H. Parker, Dashwood House, New Broad Street, London, is liquidator. A meeting of creditors will be held at Dashwood House on Dec. 8th, at 11 a.m.

A meeting of the "X" Electric Accumulator Co., Ltd., will be held at 18 Leadenhall Street, London, E.C., on December 15th, at 12 noon, for the purpose of hearing the liquidator's account of the winding-up.

A meeting of the I.T.E. Electric Co., Ltd., will be held at the offices of Mr. F. M. Jeboult, 9 Walbrook, London, E.C., on December 17th, at 10 a.m., for the purpose of hearing the liquidator's account of the winding-up.

A meeting of the Buenos Aires Grand National Tramways Co., Ltd., will be held at 62 London Wall, London, E.C., on December 16th, at 12 noon, for the purpose of hearing the liquidator's account of the winding-up.

NEW WORKS.—The new works of the Cowper-Coles Engineering Co., Ltd., at Willesden, are now in full working order. In addition to their specialities, such as pumps, indicators, and valves for circulating corrosive liquids, a new form of sand-blast machine for the removal of scale and oxide from iron and steel is being manufactured.

ROBERTSON PRIVATE FIRE BRIGADE.—At the annual tournament of the London Private Fire Brigades Association on Saturday, the Robertson Electric Lamps, Ltd., Fire Brigade won the "Nestle" Challenge Cup, the "Marshall" Challenge Cup, and the "Dewar" Challenge Shield.

MISCELLANEOUS CITY NOTES

ADELAIDE ELECTRIC SUPPLY CO.—A dividend of 6 per cent. per annum is announced on the ordinary shares for the year to August 31st.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—A dividend at the rate of 8 per cent. per annum has been declared upon the deferred ordinary stock, in respect of the June half-year.

PROVINCIAL TRAMWAYS CO.—The directors recommend a final dividend of 4s. each on the ordinary shares for the year to Sept. 30th, making a total of 7s. per share for the year. The sum of £8,000 has been set aside for reserve and depreciation, and £500 has been written off expenses of the issue of debenture stock. The sum of £2,686 is carried forward.

UNITED ELECTRIC TRAMWAYS OF MONTE VIDEO.—An interim dividend of 4 per cent. per annum, less tax, has been declared on the ordinary shares for the past half-year.

RAYWORTH'S TRACTION PATENTS.—A petition will be heard before Mr. Justice Swinfen Eady on December 7th, for the reduction of the capital of this company from £30,000 to £20,625.

Telephones in Turkey.—A Reuter telegram from Constantinople on Friday states that it is rumoured that the Commission charged with the examination of the tenders for the establishment of a telephone system in Constantinople has recommended the concession being granted to Mr. H. Laws Webb, in conjunction with the National Telephone Co., Ltd., the British Insulated & Helsby Cables, Ltd., the Western Electric Co. of Chicago, and the French Thomson-Houston Co., Ltd. The recommendation of the Commissioners is subject to the approval of the Turkish Minister of Finance, but it is stated that this is considered to be certain.

Aberdeen Telephone Exchange.—On November 13th, the National Telephone Co. transferred the subscribers connected to its Kittybrewster, Western, and Central Exchanges in Aberdeen to a C.B. equipment installed in new premises in Bon Accord Street. The new equipment has been manufactured and installed by the Western Electric Co., of North Woolwich, and is of the No. 1 C.B. type, consisting of 23 subscribers' positions, giving accommodation for 3,220 lines; three incoming junction positions, and one exchange testing position. The ultimate capacity of the switchboard is 10,000 subscribers' lines, and the equipment is of similar design to that installed at the company's Birmingham-Midland, Altrincham, Hillhead, Bromley, Dalston, and New Cross Exchanges.

The Vajen Bader Head Protector.—We have received from Messrs. Spagnoletti, Ltd. (Goldhawk Road, W.), a leaflet describing this form of protecting helmet for use in mines and in cases of smoke and fumes generally. The apparatus is much simpler in construction than most rescue outfits, and the helmet is smoke-proof and can be used with safety in all cases of dense smoke or poisonous gases. An air reservoir is fixed to the back of the head-piece, with tube connections, conducting the air to the proper point for breathing. Fresh air can be stored for sixty minutes' use, or longer if required. The helmet is always ready for instant use, is easily worn, is perfectly safe for the user, and dispenses with all outside pipes, hose, or other connection, thus giving perfect freedom of action.

COMPANIES' MEETINGS AND REPORTS

CASTNER KELLNER ALKALI CO.—The accounts for the year to September 30th show a net profit of £134,154, in addition to £15,369 brought forward. The directors place £35,000 to depreciation reserve, £1,370 in writing off the balance standing to the debit of suspense account, and £25,000 to the general reserve account. A final dividend of 9 per cent., making 14 per cent. for the year, is recommended, leaving £15,840 to be carried forward.

BRITISH VACUUM CLEANER CO.—The accounts for the year to Sept. 30th show a net profit of £757. The directors recommend the transfer of £500 to reserve fund, carrying forward the balance.

CAPE ELECTRIC TRAMWAYS.—At the annual general meeting last week the report and accounts given in our issue for November 4th were adopted. It was stated that for the first four months of the present financial year, the receipts showed an increase of £3,000 over the corresponding period of the previous year.

ADELAIDE ELECTRIC SUPPLY CO.—There was a net balance of £24,260 for the year to August 31st, and, after meeting preference dividends and a 6 per cent. dividend on the ordinary shares, the sum of £1,506 has been transferred to suspense account, £1,000 to depreciation account, and £5,000 to dividend equalisation account, leaving £1,009 to be carried forward. The total number of units sold during the year was 2,073,550, against 1,666,974 for the previous year. There are 2,369 h.p. of motors connected, against 1,837 h.p., and the total connections now represent the equivalent of 167,146 h.c.p., against 129,922 for the previous year.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—The net profits for the year ended June 30th, including the balance brought forward, amounted to £168,280. After meeting a final dividend at the rate of 8 per cent. per annum upon the deferred ordinary stock and transferring £37,329 to reserve the balance of £7,061 is carried forward.

Tramway Rating.—At the Preston Quarter Sessions on Monday, judgment was given in the appeal of the Blackpool & Fleetwood Tramroad Company upon the question as to whether their undertaking is a tramway or a railway for the purposes of rating. It has already been held by the House of Lords that so far as the line is on private property it must be treated as a railway, and rated at a quarter the full rateable value. The present dispute concerns the five furlongs of tramway in Fleetwood, the Company claiming to be assessed at a quarter the rateable value, in the same way as the tramroad portion. The Chairman of the Sessions, Mr. H. W. Worsley-Taylor, K.C., decided against the Company, on the ground that if their contention was upheld, all the tramways in the country could claim to be railways for the purposes of assessment. He granted leave to appeal.

Telegraph Traffic and Movements of Cable Ships.—The lines between Jamaica and Puerto Rico, and Jamaica and Turk's Island, are working again. The El Arich route was restored on the 23rd ult. On the same day the Rome-Constantinople line was interrupted. The Hanekine and El Arich routes were down again on the 24th ult., the trouble being between Ismid and Constantinople, and causing delay on telegrams to Syria and Irak. The line between Rome and Constantinople was restored on Friday last, and on Saturday the Indo-European Telegraph Co. restored communication between Kertch and Soukhoum-Kale. The West India system of the French Cable Co. is still in the same condition as last reported. On Monday last the El Arich and Hanekine routes were restored, but the Bagdad and Bassorah line ceased working.—The c.s. *Buccaneer*, of the India Rubber, Gutta Percha, and Telegraph Works left the Thames a few days ago for Havre, while the *Cambria* is at present off the Canadian coast repairing a break in the cables of the Western Union Telegraph Co. The mid-Atlantic break and the rupture off the Irish coast have only recently been repaired. The *Colonia*, of the Telegraph Construction and Maintenance Co. will soon leave to divert another of the cables of the Commercial Cable Co. to St. John's, Newfoundland, and the c.s. *Mackay Bennett*, of the latter company, will assist. This steamer recently repaired a break in the cable of the Direct United States Cable Co. between Halifax, N.S., and Rye Beach. The *Minia*, of the Anglo-American Telegraph Co., has arrived at Halifax, N.S. The *Contre Amiral Caubet* has remained at Halifax, in spite of the fact that four of the French company's sections are down in West Indian waters. The c.s. *Henry Holmes*, of the West India and Panama Telegraph Co., is engaged on repairs to the Jamaica-Puerto Rico cables, both of which were interrupted on the 10th ult., and repaired on the 24th. The steamer *Relay* was chartered to repair the Turk's Island-Jamaica cable, recently interrupted, and this work was successfully accomplished on the 29th ult. The breaks in the two cables to Germany from this country are also awaiting attention.—Under their new contract with the Brazilian Government, the Amazon Telegraph Company is bound to reduce telegraph charges by 20 per cent., and if the traffic increases beyond 600,000 words a year, by 30 per cent. The cables must be laid in fifteen months.

Digitized by Google

APPOINTMENTS AND PERSONAL NOTES

The Ilford Tramways Committee's recommendation that the commencing salary of the new tramway manager, Mr. Woolstencroft, be £300 per annum, rising by annual increments of £25 to £400, has been adopted.

The Electricity Committee of the West Bromwich Corporation recommend that the salary of the electrical engineer, Mr. W. A. Jackson, be increased from £300 to £350 per annum as from July 1st last.

Mr. W. S. Hind, of the sales department of the Marylebone undertaking, has been appointed Assistant Sales Manager at £4 per week without commission.

At the meeting of the West Ham Corporation last week, the recommendations of the Electricity Committee as to increases of salary, given in our last issue, were confirmed.

Mr. Frank Sydney Paterson has resigned his seat upon the board of Messrs. Johnson & Phillips, Ltd.

American Telegraphs and Telephones.—The Continental Telephone & Telegraph Co. of the United States (New Jersey), with a capital of £10,000,000, will, says the *Telegraph Age*, take over some of the principal long-distance and local independent systems in New York and the Middle West.—The Postal Telegraph and Cable Co. are constructing a new Trans-continental line of two wires connecting Salt Lake and San Francisco *via* Reno. Over a distance of 40 miles across the Rocky Mountains the poles had to be imbedded in rock, and at an altitude of 7,000 ft. Additional wires are being constructed between Seattle and San Francisco, Salt Lake City, and Denver and Omaha, and the latter place and Chicago.

Result of Patents Act.—In his Presidential Address to the Chartered Institute of Patent Agents last week, Mr. O. Imray dealt with the results of section 27 of the Patents and Designs Act, 1907. According to *The Times*, he said that in one year's working 11 patents had been revoked by consent, and four after a contest; only one patent had been revoked at the instance of a British manufacturer anxious to manufacture the patented article. The section had, however, resulted in the introduction into this country of several industries by foreigners owning British patents. He suggested that the Act should be altered so that manufacture in one country of the Patents Union should protect a patentee from the revocation of his patent in all countries of the Union.

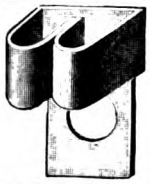
Blackfriars Bridge Subways.—On Monday last, the new passenger subways at the north end of Blackfriars Bridge were opened to the public by the Lord Mayor, Sir John Knill. The County Council contributed £30,000 for the construction of the subways. The high cost was chiefly due to the fact that an enormous number of pipes and cables had to be diverted. A description of this work, together with a sketch map of the passenger subways, the L.C.C. pipe and cable subway, and the various cable ducts was given in Electrical Engineering, September 16th, 1909, p. 809. The Post Office constructed three new lines of ducts, and lengthened and diverted 105 telephone and telegraph cables. The National Telephone Co. were obliged to move and lengthen a number of cables, while two supply companies relaid a number of mains. All this work was done without interrupting the supply or disturbing the telephone circuits.

COUNTY OF LONDON.

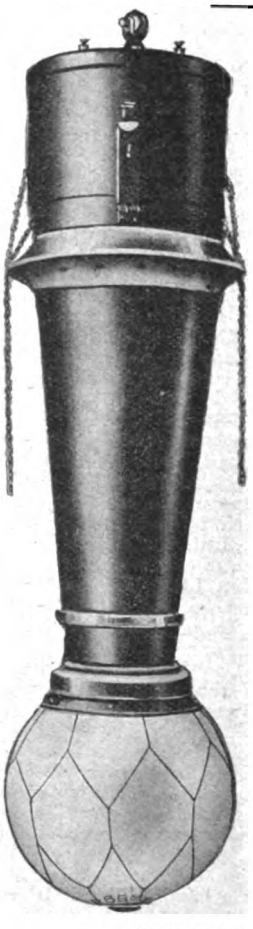
THE LONDON COUNTY COUNCIL invites tenders for the supply, delivery and erection of overhead electrical equipment for the construction on the four wire system of electric traction of the Council's tramways from Woolwich to Eltham.

Full particulars, and also information as to the conditions to be observed by tenderers, will be given in the London County Council Gazette of 6th December, 1909. The Gazette, which is published weekly, contains particulars of all the tenders invited by the Council, and can be obtained from Messrs. P. S. King & Sons, 2 and 4 Great Smith Street, Westminster, S.W., price 1d., post free 1½d. an issue, or for the whole year a prepaid subscription of 6s. 6d.

Tenders must be upon official forms to be obtained from the Clerk of the Council, County Hall, Spring Gardens, S.W., upon payment to the Cashier of the Council of the sum of £2 for the specification, etc. This deposit fee will only be returned if a *bona fide* tender is submitted. No tender received after 11 a.m. on 14th December, 1909, will be considered.



The Council does not bind itself to accept the lowest or any tender, and it will not accept the tender of any person or firm who shall on any previous occasion have withdrawn a tender after the same had been opened, unless the reasons for the withdrawal were satisfactory to the Council.



G. L. GOMME,
Clerk of the London County Council.

A METHOD OF CHARGING FOR SMALL LIGHTING CONSUMERS

IN a Paper read before the Institution of Electrical Engineers on Thursday last, and entitled "The Present Aspect of Electric Lighting," Messrs. H. W. Handcock and A. H. Dykes again brought up the question of the influence of metal filament lamps upon electricity supply undertakings, and the advisability of altering methods of charging in certain cases. After referring to the extraordinary progress made by the lamp makers in the past two years, the authors give some interesting figures for an installation of 653 lamps, one of the first to be fitted with transformers and 25-volt lamps. The change was made in April, 1908, the original 100-volt carbon filament lamps being replaced by 10 c.p. 25-volt tungsten lamps. Including breakages, the average life of the lamps had been 1,280 hours, although they were frequently overrun. In another building on the mains of the Charing Cross Supply Co., Ltd., 105-volt lamps of 25 and 32 c.p. were substituted for the original carbon lamps. At the end of 1,083 hours of actual use, out of 980 lamps installed 70 per cent. were still burning. Lamps by various leading makers were put in, so that this might be taken as fairly representative of what may be expected under ordinary conditions.

So far, continued the authors, D.C. 200-volt stations have not been much affected, but a 16 c.p., 24-watt lamp for 200 volts will be on the market very shortly at the price of 5s. The diameter of the filament is only 1/1,200th of an inch, and its length nearly 40 in. The authors have seen in operation a 10-c.p. 200-volt lamp taking only 15 watts, and it is evident that whatever has been the effect of the metal filament lamp on supply stations during the last two years, it will be greatly intensified in the near future. The results of the past two years have only served to strengthen the authors' belief that the flat rate system fails to meet the conditions that now obtain, and that only by the adoption of some system which secures a definite minimum return from each consumer based on the rate at which he contracts to take energy, can purely lighting stations be profitably run. As an example of the effect of the introduction of metal filament lamps, the case of a London suburb may be mentioned. Here, consumers' lamps averaged originally 12 c.p., and their consumption per lamp installed was 15·6 units per annum. This gave a revenue per lamp connected (averaging 12 c.p.) of 7s. 9d. On changing over to 16 c.p. metal filament lamps and a transformer, the revenue per lamp has fallen to 6s. 4d., in spite of the increase in the illumination of 33 per cent. In future the consumption per lamp installed will be of the order of 6 to 7 units, whilst in many cases it will fall to as low as 3 or 4. Even at 8d. per unit a 10-light consumer having a total consumption of 30 units per annum cannot be remunerative. In the same district the price of gas is 2s. 6d. per 1,000 cub. ft., and by the inspection of the accounts of a number of gas consumers occupying small premises it was found that the cost for lighting only, exclusive of cooking, but including the meter rent, averaged 12s. 2d. per burner per annum, whilst many were as high as £1.

Comparing short- and long-hour consumers, the authors assert that the very short-hour consumer can never be a remunerative one on the present flat rates, as the capital outlay to supply him is very nearly the same as for a long-hour consumer, and suggest altering the charges at the short-hour consumer's expense in order to attract the long-hour consumer. In the case of the suburban system referred to above, they continue, the standing charges per kw. of consumers' demand amount to £17, and the running costs 0·4d. per unit. Assuming that under new charges 80 per cent. of the lamps installed would come on the peak (the average at present is 30 per cent.), the standing charges per 30-watt lamp would be:—$\frac{£17 \times 20 \times 30}{1{,}000} \times 0{\cdot}8 = 8$s. 2d., and if the lamps were used for 400 hours the running charges would be $\frac{400 \times 30}{1{,}000} \times 0{\cdot}4 = 5$d.; a total of 8s. 7d. If they were used for 2,000 hours the running charges would be $\frac{2{,}000 \times 30}{1{,}000} \times 0{\cdot}4 = 2$s., or a total of 10s. 2d. Whether the lamps be used for 400 or for 2,000 hours, therefore, only makes a difference of 1s. 7d. The difference in cost is so little, and the business advantages, from the point of view both of the station and the consumer, of a fixed charge are so great, that the authors consider it preferable to make a fixed charge per lamp per annum, irrespective of the number of hours during which the lamps are used. The consumer may be prevented from substituting larger lamp units by using special lamp-holders such that only lamps which are sold by the station or its agents can be used. The authors believe that all stations having normally low running costs could, with advantage to themselves, supply the long-hour consumer, who at present generally uses gas, at a fixed charge per lamp per annum, which would be well below what he is at present paying. The price will naturally vary for each district, but a fair average, inclusive of wiring rental, appears to be 12s. per 30-watt lamp per annum for a continuous supply, and 10s. per annum for a "dusk to dawn" supply. This "Contract" system is quite distinct from the Contract Demand system. Mr. Wilkinson, of Harrogate, who supplies on the contract system, charges small consumers by a fixed sum of 11s. per lamp per annum. A short time ago, continued the authors, the inhabitants of a certain district were informed that the local Electric Light Co. would wire their house free, and make an inclusive charge of 10s. per lamp per annum to cover the wiring rental and the right to use the lamps as required from dusk to dawn, and during periods of unusual darkness, and the result of this was that signed applications for some 2,000 lamps were obtained. In the future, purely lighting stations will be forced to undertake the wiring of houses and to supply lamps, and any improvement in the efficiency of the lamp will be of benefit to the stations, and not, as at present, a loss to them. On A.-C. systems some form of concentric wiring with earthed outer is the cheapest, and the cost of a double-wound transformer is now so low that the saving on the first cost of the lamps is sufficient in most cases to cover it. The great majority of small consumers, the men who burn their lamps long hours and pay the gas company anything from 12s. to £1 per lamp per annum, live in terrace houses. A whole terrace could be wired from a single transformer fixed on the outside wall of the building. The transformer can reduce the pressure to 50 or 100 volts on either side of a three-wire circuit, the neutral of which is earthed. From the transformer the concentric wires can be neatly cleated to the outer wall and looped into each house in turn. In this way the service charges per kw. of consumers' demand can be considerably reduced, and the wiring can be brought down to 10s. to 12s. per light, or, say, 1s. 3d. per annum for upkeep, interest, and sinking fund. Even where the standing charges amount to £17 per kw. of consumers' maximum demand, and allowing for 80 per cent. of the lights installed being on at once, a 30-watt lamp can be supplied for from 8s. 7d. to 10s. 2d., or, including the free wiring, for 9s. 10d. to 11s. 5d. per annum. It is not likely that the average burning hours will be as high as 2,000, so that an ordinary long-hour consumer can be supplied for a sum not exceeding 10s. to 12s. per 30-watt lamp. As it is not necessary to put 30-watt lamps in the smaller rooms, a 10s. inclusive charge would in many cases be amply justified.

In suburban and country districts, with a small A.-C. station, continued the authors, great economies can be effected if a supply be only given from dusk to dawn, the station being shut down during the daytime. In addition to the saving in labour at the station, the limited hour supply reduces transformer losses and also prevents any waste of current during the daytime. By using internal combustion engines, current can be quickly turned on in the case of fog or unusual darkness, under which conditions a supply is given. In three districts for which Provisional Orders have been recently obtained, it is proposed to work on this plan, and the necessary consents have in each case been given by the local authority. To meet the difficulty that arises through consumers wanting to instal lamps which are rarely used, the authors propose to use a limit indicator, and to charge the consumer 12s. per 30-watt lamp, calculated on the number to which the limit indicator is set, and 2s. per lamp on the remainder to cover the wiring charges.

Concluding, the authors suggest that in a very few years supply mains will be extended into districts now neglected because they only contain small houses. The generating stations will use internal combustion engines, which, in many cases, will only work during the hours of darkness, the supply being single-phase at about 2,000 volts. Scattered houses will be supplied from transformers fed by tappings direct off the 2,000-volt mains, and the more thickly populated districts off the low-tension networks. The interior wiring will be put in by the supply company or their agents, and will be "earthed return." There will be a fixed inclusive charge of about 2s. 6d. to 3s. per lamp per quarter, paid in advance.

There are three appendices to the Paper. The first contains a number of typical gas consumers' accounts, and the second gives the probable capital cost and running expenses of a lighting system for 10,000 lights for a dusk-to-dawn supply as proposed in the Paper. The receipts are reckoned at 10s. per lamp per annum at £5.000, while the working expenses amount to only £1.896. Adding 3 per cent. for sinking fund, a total

Digitized by Google

of £2,592 is arrived at, leaving a net result on the total outlay of £23,210 of £2,408. The third appendix contains a comparison of figures of an existing undertaking with what they would be if it were supplying at 12s. per 30-watt lamp per annum without meters. The present figures are :—Flat rate approximately 5d. per unit, 54,000 30-watt (equivalent) lamps connected; maximum load, 560 kw.; units sold, 600,000. Expenditure on services and meters, £7,800=2·9 shillings per 30-watt lamp. 23,000 lamps are "free wired" at present at an average cost of just over £1. Gross revenue, including meter rents and wiring rentals, £13,000. Running costs, 0·44d. per unit. The figures on the contract system at 12s. per lamp are as follows :—Assume that 80 per cent. of all lamps connected came on the peak, and that the lamps are run on an average as much as 1,500 hours per annum. The capacity of the station thus becomes : 23,300 30-watt 25-c.p. lamps. The revenue at 12s. per lamp per annum is £13,980. The output is now

$$\frac{23,300 \times 1,500 \times 30}{1,000} = 1,048,000 \text{ units},$$

an increase of 448,000 units, which at 0·44d. equals £821. This gives a net increased profit of £159 plus the saving by the abolition of the meter department, and the sum available for services per lamp connected is now $\frac{£7,800}{23,300} = 6·7$ shillings.

DISCUSSION.

Mr. G. Wilkinson (Chief Electrical Engineer, Harrogate Corporation) said that about half the lamp connections to his mains were now metal filament lamps, but in spite of this he found that, for the seven months of the present financial year, the units generated were only 2 per cent. less than in the corresponding period of the previous year. With regard to tariffs, it was imperative, if any profit was to be made for small consumers, that there should be a fixed charge per lamp. At Harrogate the fixed price was 2s. 9d. per lamp per quarter, or 11s. per annum, per 30-watt lamp, which compared with 7s. 7d. per 30-watt lamp, which was the average paid by a large number of consumers on the maximum demand system. This left a good margin. He knew of cases where consumers desired to give up their meter and go on to the new system, in spite of knowing they would have to pay more, for the reason that they would know exactly what they had to pay. The Harrogate cost for standing and running charges were slightly better than the total of 8s. 7d. mentioned in the Paper, but even on this figure, if a consumer used his lamps for 2,000 hours per annum, the running charges were only increased from 5d. to 2s., making the total 10s. 2d., which still left a profit on the price charged at Harrogate. The Harrogate consumers' agreement consisted of three conditions. First, current is only to be used in the evening, and at such periods of the day when ordinary occupations cannot be carried on; second, current is to be used for lighting purposes only; and, third, the apartments in which the lamps are fixed must be satisfactorily illuminated by daylight during daylight hours. He installed a current limiter, which set up a blinking of the lights immediately the contract demand was exceeded. The authors referred to wiring at 8s. 6d per point, but at Harrogate they could do the wiring, including pendant, shade, and limiter, at 5s. 6d. per point. The cost of services at Harrogate was from 50s. to 60s., including a limit indicator. No arrangements were made for heating and cooking; this was waste of time in such districts as those being dealt with. He exhibited a current limiter which was compensated so that atmospheric temperature did not have any effect upon it (*see* Electrical Engineering, Nov. 11th, page 974).

Mr. R. C. Pierce (Manager and Engineer, Cambridge Electric Supply Co.) said he found it difficult to reduce the cost of wiring below £1 per point, including a metal filament lamp, a plain pendant, and the necessary transformer. At Cambridge, since the introduction of metal filament lamps, no less than 6,000 30-watt lamps had been added, and with some system of rental such as that suggested he had no fear for the future.

Mr. W. R. Cooper mentioned that the system had been used on the Continent, and foresaw trouble in preventing consumers adding to their installations. 25-volt circuits, he said, entirely eliminated the possibility of applying electricity to cooking and heating purposes. Station engineers complained of their bad load factors, but 25-volt circuits would cut them off from the possibility of a remedy. Would it not be worth while to consider the advisability of running 100-volt circuits on overhead wires, as on the Continent? He thought the custom of using high candle-power metal filament lamps with clear globes would eventually have very deleterious effects upon the eyes. The intrinsic brilliancy of an ordinary gas flame was 20 candle foot per square inch; of an incandescent gas mantle 35 candle foot; of a carbon filament lamp 540 candle foot, and of a metal filament lamp about 1,000 candle foot per square inch. There was only a saving of 5 per cent. in cost by having clear globes.

Mr. C. H. Wordingham said that personally he should have thought an apology was necessary for bringing such a Paper forward at this period. The subject of methods of charging was the stalest of the stale, and, since Dr. John Hopkinson's classical Paper in 1893, not a single new thing had been written about the matter. Dr. Hopkinson showed conclusively that the only method of charging was a sliding scale. Unless this were done, they could never hope to compete with gas. It was ludicrous to charge the long-hour consumer the same rate as the short-hour consumer. He entirely disagreed with the contract rate proposed in the Paper. It was altogether unsound. The system had been tried by the London Electric Supply Corporation, but it was not a success. The authors' suggestion to specify a special form of lamp-holder was absolutely illegal. He also disagreed with the proposal to shut down stations in the middle of the day; the revenue in his own case would be reduced by one-fifth or one-sixth, because he used radiators. The primary thing for a central station man to aim at was continuity of supply.

Mr. A. H. Seabrook (Engineer and Manager, Marylebone Electricity Undertaking) agreed with the principle of the small fixed charge and a charge per unit. There were hundreds of consumers in every district who used both gas and electricity, gas being used in the daytime and electricity at night. With a contract demand system it did not pay consumers to use gas, because it could not compete with electricity at 1d. per unit. In his opinion there was a great future for cooking and heating apparatus. In Marylebone their own sales, after a few weeks, had amounted to £250 a week, which only included a small portion of the business available. This also meant revenue from energy consumed, and when that was fully realised he did not think many station engineers would leave this branch of the business alone.

Mr. J. S. Dow said that under any such system as proposed in the Paper, the consumer should have the right to ask for some sort of measurement to see that he is getting what he bargained for. With regard to the authors' conclusion that no gas company could afford to utilise such a system, he was informed that gas companies could afford it perfectly well, but would not, because they had such a convenient method of charging at the present time. The system had been tried in the case of gas, but had been dropped because it could not be applied to heating.

Mr. H. T. Lewenz spoke of the advantages which would accrue from a general standardisation of distributing voltages, wiring cable and fittings. It would increase the use of electricity for the reason that it would remove a good many of the difficulties which they were now discussing.

Mr. K. A. Scott Moncrieff (Electric Supply Corporation) said in most old-fashioned small towns there was a good deal of all-day lighting by gas, and it would be a good thing to get this by offering a contract demand system, leaving the ordinary lighting to be dealt with by meter. He confirmed Mr. Wilkinson's figure for cost of services. He had had no difficulty, with about 10 to 15 yards run service cable, in doing it for £3.

Mr. T. Risch remarked that the authors practically said that the small consumer, whom they had all been looking to, was unremunerative. He did not agree with the contract demand system, but would rather put in larger meters than the present installations warranted, so that heating and cooking apparatus could be used as time went on. The gas company did not scoff at the small consumer, but gave him a slot meter, with excellent results. He would like to see the Institution take steps to remove the Local Government Board rule that meters must be paid for out of revenue.

Mr. Hugo Hirst (General Electric Co.) repeated what he said 18 months ago in relation to metal filament lamps, viz., that there was no need for panic measures. Mr. Wilkinson's remark that his output was only 2 per cent. less amply justified this. The lamp-maker's experience was that there is a growing demand for large candle-powers, and when a cheap wiring system was available, together with a better supply of lamps, they would be in a still better position to continue the already successful attack upon the gas companies.

Mr. P. D. Tuckett (Edmundsons' Electricity Corporation) asked the authors to explain how they proposed to force the fixed charge system upon consumers?

Mr. H. W. Handcock, in reply, said that the difficulty of preventing people increasing the size of their lamps was partly overcome by the fact that this would be stealing electricity, which was now a felony. Many speakers seemed to think it was the intention to put all consumers on to this system at once. It was not. The authors' claim was that under the conditions now prevailing with metal filament lamps, electric supply undertakings were now able to supply a large number of the present gas consumers with electricity at a lower price. Existing consumers would be given the option of continuing on the existing system. A large unexplored gas field had been opened up since the advent of the metal filament lamp. From the authors' point of view the small consumer was the residential consumer with the big number of lamps running only a few hours per day, and the big consumer was the man with a few lamps burning long hours. The latter should not be burdened with restrictions such as meters. With regard to overhead wires, the chief difficulty was not with the Board of Trade, but with the local authorities and county councils. Consistent with public interest and with existing Acts of Parliament, nobody ever knew the Board of

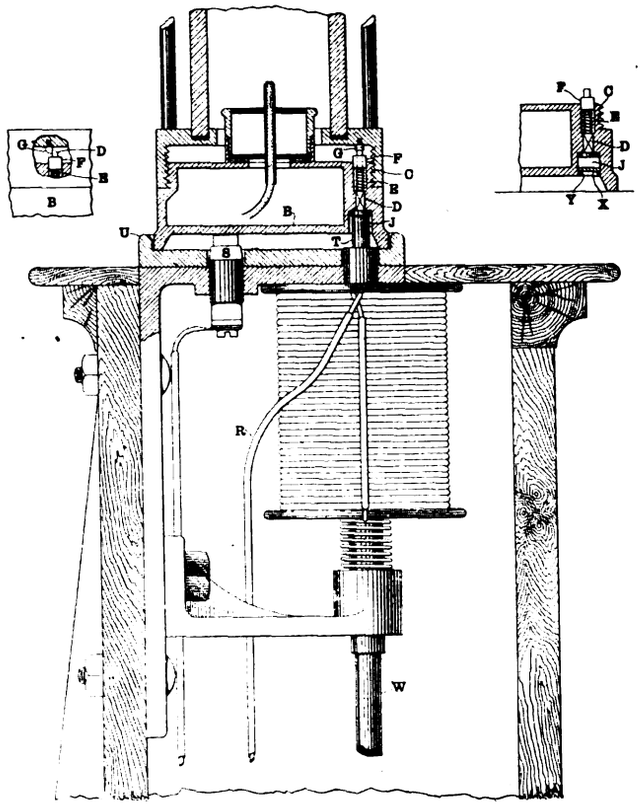
Digitized by Google

Trade to do anything to bar progress. The contract system could be enforced by giving consumers the option of a flat rate at the maximum charge in the schedule to the Order, which was usually 8d. per unit. As to prescribing special lamp-holders being illegal, under the Electric Lighting Acts, agreements could be entered into between consumers and the supply authority, provided other consumers under similar circumstances were offered the same terms.

The PRESIDENT, in proposing a vote of thanks, mentioned that a contract system had been adopted in a little town in Upper Italy, where he had been a consumer. No "blinkers" were put in, and the contract was for a maximum number of amperes at a fixed voltage. A meter came into action when the current consumed exceeded the contract. He was told by one of the authors that they were putting in 10,000 lamps upon their system, and he was sure they would all wish them a very successful result.

International Conference on Electrical Units and Standards.—An appendix to the report of the International Conference on Electrical Units and Standards, 1908, has been issued, containing some notes to the specifications as to the methods adopted in various standardising laboratories to realise the International Ohm and the International Ampere, and to prepare the Weston normal cell. It includes a long contribution by Messrs. F. A. Wolff and C. E. Waters on the methods adopted by the American Bureau of Standards in the preparation of the Weston normal cell, an account of the procedure adopted in the setting up of the same at the Laboratoire Central d'Electricité, Paris, and notes from the Physikalisch-Technische Reichsanstalt, on mercury standards of resistance, the deposition of silver, and the Weston cell. These subjects are also treated by the National Physical Laboratory, and the publication concludes with a bibliography of literature relating to electrical standards.

Speed Indicators for Tramways.—A special committee of the Tramways and Light Railways Association appointed to consider this matter has drawn up a set of conditions in regard to the loan of instruments from manufacturers for trial purposes, copies of which have been sent to the manufacturers who expressed their willingness to submit instruments, and the indicators have been allotted to different members of the Association. The members of the special committee are:—Mr. H. England, General Manager, Wakefield Tramways; Mr. C. W. Mallins, General Manager, Liverpool Tramways; Mr. A. H. Pott, Chief Engineer, Metropolitan Electric Tramways; Sir Clifton Robinson, Managing Director, London United Tramways; Mr. J. R. Salter, General Manager, Lancashire United Tramways; and Mr. S. Sellon, representing several tramway undertakings.



The Sale of Leblanc Condensing Plant.—In the Appeal Court on Tuesday, Mr. Victor H. Coates appealed against a decision of Mr. Justice Sutton, in chambers, refusing to appoint an arbitrator under an agreement between Mr. Coates and the British Westinghouse Co. It appears that an agreement was entered into between the plaintiff and the Société Anonyme Westinghouse, appointing him sole agent in this country for the sale of Leblanc condensing plant. The British patents were subsequently taken over by the British Westinghouse Co., and Mr. Coates contended that the agreement between him and the French Westinghouse Co. was binding upon the British Westinghouse Co. The latter denied this, and argued that, there being no agreement, no arbitrator could be appointed. The Court held that Mr. Coates must first take action on the question of whether the agreement was binding on the British Westinghouse Co., and in the circumstances dismissed the appeal with costs.

The Andrew Carnegie Research Scholarship.—A research scholarship or scholarships, of such value as may appear expedient to the Council of the Iron and Steel Institute from time to time, founded by Mr. Andrew Carnegie (past-president), who has presented to the Iron and Steel Institute one hundred thousand dollars for the purpose, will be awarded annually, irrespective of sex or nationality, on the recommendation of the Council of the Institute. Candidates, who must be under thirty-five years of age, must apply on a special form before the end of February to the Secretary of the Institute. The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students, who have passed through a college curriculum or have been trained in industrial establishments, to conduct research in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. There is no restriction as to the place of research which may be selected, whether university, technical school, or works, provided it be properly equipped for the prosecution of metallurgical investigations. The appointment to a scholarship shall be for one year, but the Council may at their discretion renew the scholarship for a further period instead of proceeding to a new election. The results of the research shall be communicated to the Iron and Steel Institute in the form of a Paper to be submitted to the annual general meeting of members, and if the Council consider the Paper to be of sufficient merit, the Andrew Carnegie gold medal shall be awarded to its author. Should the Paper in any year not be of sufficient merit, the medal will not be awarded in that year.

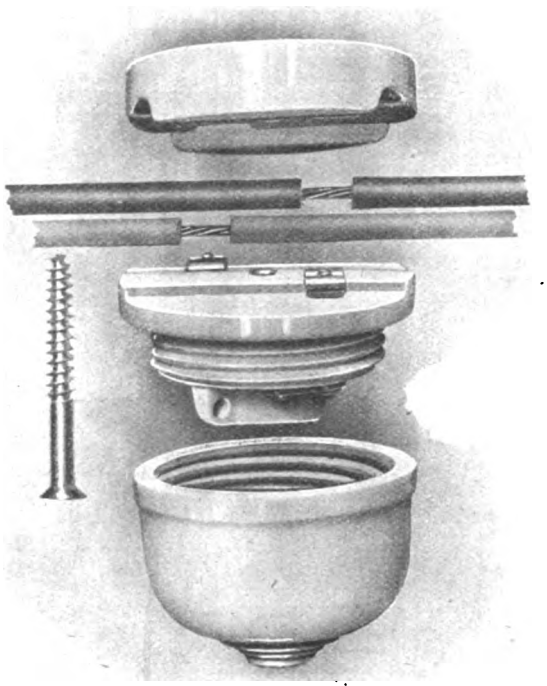
MAGNETIC LOCKS FOR MINERS' LAMPS

A PATENT of some considerable importance to mining engineers expires to-morrow, after having run its full life of fourteen years. This patent covers a locking device for miners' lamps, comprising a vertical spring bolt passing through the lamp bottom, and so arranged that it can only be moved so as to release the lock by means of a special electromagnetic opening appliance. The owners of the patent (No. 23,127 of 1895) are Messrs. Ackroyd & Best, Ltd., Morley, nr. Leeds.

In the accompanying illustration reproduced from the patent specification, *B* is the lamp bottom, which is screwed into the frame, and *D* is the bolt which is held upwards by the action of the spring *E* on the nut *F*. The upper end of the bolt engages with a projection *G* on the lamp frame, and the edges of both are rounded off, as shown in the detail drawing, so that they pass each other when the bottom is being screwed in. When the lamp bottom is screwed completely home, the bolt recedes, passes beneath the projection and rises on the other side, thereby locking the lamp. By having the enlarged head of the bolt well within the recess *J*, the bolt cannot be withdrawn by means of any tool. The opening appliance comprises a box containing a battery, to which is connected the electro-

SECTIONAL VIEW OF MINERS' LAMP AND MAGNETIC UNLOCKING DEVICE (ACKROYD & BEST, 1895 PATENT).

magnet *R* through the push-button switch *S*. The magnet core *T* and the button of the switch both project upward through a ring *U*, which fits over the lamp bottom. On placing the lamp in the ring, the magnet core comes in contact with the bolt *D*, and, the push-button switch being depressed, the magnet is energised. The bolt is then drawn down slightly so as to unlock the lamp by depressing a treadle attached to the rod *W*, which is an extension of the magnet core. If desired, the push-button switch can be actuated separately by the operator. To protect more completely the bolt *D*, a sliding disc *X* is inserted in the recess *J*, so that in its normal position it rests on a seat *Y*, as shown in the right-hand detail drawing.



In order to facilitate the rapid connection or disconnection of the lamp parts, the interior of the frame is provided with a helical incline of a half or one turn in length. Corresponding projections are provided on the lamp bottom, and a short twist firmly clamps the two parts together. Alternatively, portions of the screw thread on the lamp bottom are cut away diagonally to the line of the thread, and the interior thread of the frame is also cut away to allow of the passage of the sections of thread on the bottom. The lamp bottom can thus be inserted to almost the full distance and clamped by giving it a short turn only.

THE VERNEY-BAZELL CLEAT CEILING ROSE

SOME further particulars are to hand of the Verney-Bazell ceiling rose, referred to in our Patent Record last week. This fitting is adapted for use in conjunction with all systems of cleat wiring, and is also applicable to any other system. As shown in the accompanying figure, the rose consists of three parts, a back plate with grooves for the cables, a body carrying terminals, and a cover The terminals are provided with binding screws on the face, and clips having lateral slots for the main wires on the back. In fixing, the main wires are merely bared of insulation, slipped under the clips, and screwed up. The body is screwed to receive the usual cover plate, and there is a central hole provided for the fixing screw. A rib formed on the back of the body, and a recess in the face of the base, ensure the centreing of the base. Ridges and slots are made for drainage of any moisture which may accumulate in damp positions.

It is stated that installations fitted with these roses give a

Verney-Bazell Cleat Ceiling Rose.

higher insulation test, owing to the cables and terminals being completely enclosed in porcelain. They also avoid the necessity of looping in, and the chance of the wire being nipped or broken in twisting up. Another feature is the great saving of time. It is asserted that a wireman is able to fix, in the course of a day, three times the number of roses which could be fixed under the old method, and also to effect a very great economy in material. The rose can be adapted to casing by the use of short bridge pieces.

Orders have already been received from several breweries, rinks, works, railway companies, and contractors, by Messrs. Loxley & Co., Ltd., Cabinet Chambers, Basinghall Street, Leeds, who are at present the sole vendors of this ceiling rose.

Lectures on Telegraph and Telephone Theory.—A special advanced course of lectures for postgraduate students, telegraph and telephone engineers, and electrical engineers on "The Theory of the Propagation of Electric Currents in Telegraph and Telephone Cables and in Electric Conductors" will be delivered by Prof. J. A. Fleming, at University College, beginning on January 19th.

Rating of Electric Power Companies.—At the Durham Quarter Sessions last week, the Cleveland & Durham Electric Power Company appealed against the rate levied by the Assessment Committee of the Lanchester Union in respect of cables laid within the Medomsley parish. The amount involved was only £82 10s., but the case is regarded as a test case, inasmuch as the Company is extending its operations into a large number of small parishes, where it is liable for rating. The company claim that the business of supplying these outlying villages is actually involving a loss, and therefore they ought not to be rated.

AN ELECTRIC HOME

THE South Metropolitan Electric Light & Power Co., Ltd., have opened a permanent exhibition of the domestic applications of electricity in the form of a model electric home at "Electra House," 111 Bromley Road, Catford, S.E. The house has been furnished in an artistic manner, and has been fitted up with all the latest electrical domestic appliances. Besides the domestic quarters, the house contains three reception rooms and five bedrooms. It is inhabited by a family, the members of which will show visitors over the rooms and explain the various appliances which will be in daily operation, no gas or coal being used in the house. All lighting, cooking, and heating is carried out electrically, as well as the supply of hot water, and among the auxiliary appliances are an electrically operated "Daisy" vacuum cleaner, sewing machine, flat irons, boot and knife machines. The supply is 200 volt A.C.

In the kitchen is a 300–1,000 watt "Tricity" cooker, a Bastian 400–1,500 watt quartz hot-plate and oven, Phœnix grills and frying-pans, and a 1,200 silundum oven. In the scullery is a Phœnix five-gallon water heater and a Fuller geyser. The hall lavatory also has a Fuller geyser (J. G. Fuller & Son), and there is a 200-watt Therol water heater (Spagnoletti, Ltd.) in the bath-room. The dining-room table at the time of our visit was laid out for tea, and the various hot-plates, kettles, &c., were connected severally to a species of distributor on the table, which was supplied from a wall plug by a flexible passing down the table leg and under the carpet. Fans, cigar lighters, reading lamps, and other electrical luxuries are in daily use, and an interesting feature not yet complete is the clock installation, neat dials in all the rooms being controlled from a Lowne master-clock in the hall. Most of the wiring is on the Simplex steel conduit system, but the kitchen is wired on the Siemens O.S. system. All the front rooms have 200-volt metal filament lamps of various makes, but the kitchen and other rooms at the back of the house are fitted with 50-volt lamps on another circuit supplied from a 500-watt transformer with an automatic switch. The rooms are interconnected by Sterling miniature telephones, and the bedroom lamps have dual control from the side of door and bed. A number of different firms' lighting fittings and radiators are in use. The drawing-room contains Lux candle fittings, and a cabinet containing china is provided with concealed lighting. Other features are the portable radiators, a bedroom watch which throws a reflection of the dial on to the ceiling, the 50-volt metal filament lamps in the cupboards, curling-tong and shaving-water heaters, an electric egg boiler, a dinner gong, bed-warmer, hot-water jugs, portable lamps, Martin lamp regulators, &c.

The home may be inspected under working conditions at any time by residents in the South Metropolitan Co.'s supply district, who should write to the company's offices for a card of admission. Separate meters and fuses are provided for heating, cooking, and lighting, and careful records will be kept of the energy consumption and the total cost of carrying out the domestic work electrically.

Among other firms whose specialities are represented are Messrs. A. P. Lundberg & Sons (wall sockets, &c.); Simplex Conduits; Electric & Ordnance Accessories Co. (heating appliances); Siemens Bros. Dynamo Works (lamps and fittings); Siemens Bros. & Co. (O.S. wiring); Neville, Williams & Co. (transformer); Marryat & Place (boot-polishing machine); Sunbeam Lamp Co.; G. M. Boddy & Co. (lamps); and others. The installation was carried out by Rowland & Hulton, Ltd. (62 King William Street, E.C.)

Electrical Football League.—The second annual concert and distribution of prizes will be held on Saturday, December 11th, at the Brook Green Works, Hammersmith, by kind permission of the directors of Messrs. Robertson's Electric Lamp Works, Ltd.

Obituary.—We regret to record the death on November 10th, in Berlin, of Herr Ernst Richter, chief engineer of Messrs. Siemens & Halske, and a director of the Siemens-Schuckertwerke, of Berlin. Herr Richter was born in 1851 in Freiberg, Saxony, was educated in Leipzig and Dresden, and in 1878 entered the firm of Siemens & Halske.

Industrial Education and Apprenticeship.—A meeting will be held at the Mansion House to-morrow (Friday), at 3 p.m., to discuss the question of industrial training in education and the development of trade schools. The meeting will take the form of a conference, at which there will be present the Right Hon. the Lord Mayor of London, Members of the London County Council, the City Corporation, and representatives of the Board of Trade, the Board of Education, the Charity Commission, the London Chamber of Commerce, City and Guilds of London Technical Institute, and the City Parochial Foundation. The position of apprenticeship and apprenticeship charities will be discussed, and the desirability of the establishment or development of employment bureaux for bringing those leaving schools into touch with the industrial and commercial world will be taken into consideration.

PHOTO-TELEGRAPHY.

On Wednesday of last week at the Royal Society of Arts, Mr. T. Thorne Baker read a Paper on photo-telegraphy. He first described the Korn system (see Electrical Engineering, November 14th, 1907, p. 767), in which the variation in resistance of a selenium cell under the influence of light of varying intensity is utilised to transmit a current inversely proportional at any instant to the density of that portion of the photograph being transmitted at that instant. The arrangements for compensating for the inertia of the selenium cell, and the construction of the receiving instrument were also described. The latter comprised an electromagnet with holes through the poles, through which passed two fine silver wires. A small shutter attached to the wires was moved in and out of the path of a ray of light focussed upon a receiving plate in accordance with the reaction between the line current in the silver wires and the magnetic field. This system had been used successfully between Berlin, Paris, and London, and in spite of considerable troubles due to induction effects on the submarine telephone cables which were used, the Paris photo-telegraphic pictures had been frequently reproduced in the *Daily Mirror*.

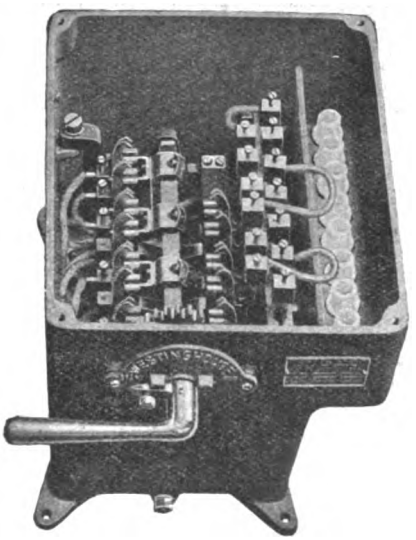
Mr. Baker then described the Caselli transmitter, in which the picture to be transmitted consisted of interrupted lines of shellac on a metal drum which revolved spirally under a style. Every time a gum line passed the style, the circuit was broken. Korn had used this transmitter in conjunction with a modified form of his shutter galvanometer. After describing the method employed in the Korn, Belin, and Thorne Baker systems for running the transmitting and receiving drums synchronously, Mr. Baker pointed out that as the transmitting foil contained a definite number of lines to the inch, there was a tendency for the regular train of electrical impulses set up to make the receiving galvanometer swing with that frequency independent of the irregularities of the lines and thus to spoil the result.

The lecturer then briefly described the Belin system, in which the varying thickness of a gelatine relief photograph was caused to bend a telephone diaphragm by means of a style, the resulting varying current in the telephone circuit operating a Blondel oscillograph. The latter reflected a beam of light through a lens of graded transparency on to a sensitive film. Finally, Mr. Baker gave some particulars of his own instrument, the "Telectrograph," described in Electrical Engineering, August 5th, 1909, p. 697. The photograph is transferred on to a lead foil with gum lines pressed in, and is received on a prepared paper sheet by electrolytic action as in the Bakewell telautograph. A dot appears each time the sending style is between two lines. A weaker current also flows through the receiving style and drum in the opposite direction. The battery used to supply this current is divided into two components. In series with each is an adjustable inductance and an adjustable resistance, one end of each resistance being joined; one end of each battery goes to the receiver, so that the whole acts as a shunt on the line. Between the sliding contacts of the resistance is a variable capacity. It was evident from line tests that secondary surges were set up differing in phase from the original waves, since without the balancer there was an elongation of each dot. By adjusting the "balancer" it is easy to make the dots come crisp and clear. The necessity for the variable condenser only became apparent when it was attempted to transmit pictures by the telectrograph from Paris to London over a submarine cable. Concluding, Mr. Baker said that he thought Prof. Korn would be likely to succeed in telegraphing pictures from New York to London by means of his selenium apparatus, but that he himself was trying to solve the problem by means of wireless operation.

In the ensuing discussion, Mr. T. Bolas asked for information with regard to the speed of the process, to which Mr. Baker replied that it now only took 25 minutes to prepare the transmitting foil from the photograph, and only 30 seconds to put it on the drum. During the recent Steinheil trial in Paris, photographs had been taken in Court late in the afternoon, and were over in London the same evening. Sir H. T. Wood doubted whether there was any great commercial value in being able to transmit pictures, but Mr. Baker thought that it would always be used for journalistic work, as the public now demanded photographs and would not have sketches. Mr. Charles Bright supported this latter view, and referred to the possible use of the system for military and criminal investigations.

Accident at the Winnipeg Electricity Works.—*The Times* correspondent at Ottawa reports that an accident in the power house of the Winnipeg Electric Company has deprived that city of practically all motive power, and necessitated the shutting down of all mills, factories, and elevators except those worked by steam. From 12,000 to 15,000 persons are idle. The electric trams are only running for two or three hours daily.

CATALOGUES AND PAMPHLETS, &c., RECEIVED



[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

LOW-TENSION OIL CIRCUIT BREAKERS.—A card from Messrs. Cowans, Ltd. (Springfield Lane, Salford, Manchester), illustrates their latest pattern of low-tension oil circuit breaker for mine and workshop use, which can be fitted with overload trip on one or two poles, and is listed up to 500 amperes at 600 volts.

ELECTRIC HEATERS.—An attractive catalogue from the British Prometheus Co. (Salop Street Works, Highgate, Birmingham) illustrates a large number of designs of convectors and radiators of the company's manufacture. The convectors include some five new designs in the Adam's style, and an innovation in the use of bead screens with radiators. We have already referred to the extensive line of heating apparatus in connection with recent publications of Messrs. Simplex Conduits, Ltd., who are the company's selling agents in the South and West of England.

MOTOR STARTERS AND KNIFE SWITCHES.—Two new leaflets from the Electrical Co., Ltd. (121-5 Charing Cross Road, W.C.), deal respectively with open, semi-enclosed, and enclosed type motor starters for motors up to 25 b.h.p., and knife switches with and without quick break attachment of various forms.

STARTERS AND CONTROLLERS FOR INDUCTION MOTORS.—The British Westinghouse Electric & Manufacturing Co., Ltd., Trafford Park, Manchester, have sent us copies of a number of new leaflets relating to starters and controllers for two- and three-phase induction motors. For very small squirrel-cage motors, a resistance is inserted in the primary circuit during starting. The circular switch and the resistance are enclosed in one compact fireproof case, and easily replaceable resistance units are employed. For motors from 5 to 80 h.p. a series of two-, three-, or four-speed starters, for altering the

Westinghouse Oil-immersed Auto-starter.

effective number of stator poles, have been introduced both in the switch and drum forms, and all except the smallest oil-immersed, to be suitable for fiery mines. Several patterns of star-delta and series-parallel starters are also listed, and main reversing and direct starting switches are standardised in both oil-immersed and non-oil-immersed types up to 70 amperes and 1,000 volts. There are also several designs of auto-starters, with switch and auto-transformer in the same case. One of these, of the oil-immersed pattern, is illustrated herewith.

IRONCLAD SWITCHES, FUSES, AND STARTERS FOR A.C. MOTORS.—Messrs. George Ellison (Victoria Works, 17 and 18 Warstone Lane, Birmingham) have sent us a leaflet giving particulars of some special designs of ironclad switches suitable for mills, factories, &c., some combined with fuses, and all interlocked so that the covers cannot be opened unless the switch is in the "off" position, nor can the switch be closed if the cover is open. Complete motor panels, with or without watertight ammeters, are also made embodying these switches. The firm are also issuing a coloured calendar for December, illustrating one of their A.C. starters with automatic releases.

Royal Assent.—The Electric Lighting Acts (Amendment) Act, 1909, and the Colinton Tramways Order Confirmation Act, 1909, received Royal Assent on Wednesday last week.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Nov. 25th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

16,285/08. **Automatic Change-over Switch.** Chloride Electrical Storage Co., Ltd., and A. Imbery. A two-way switch for automatically changing over a circuit from the main supply source to an auxiliary source on failure of the first, is normally held in one position by an electromagnet connected in shunt with the main circuit. On a failure of the supply, a weight or spring moves the switch so as to connect the circuit with the auxiliary source of supply. Three claims, three figures.

23,413/08. **Wiring System.** A. E. Lamkin and T. R. Nunwick. Two or more tubular conductors are buried in an insulating composition in conduit or casing. Joints are made by means of straight, elbow, or tee-pieces, the ends of which fit over the conduit. These pieces contain wire conductors, also embedded in insulation, the pointed ends of which project out, and are forced into the ends of the tubular conductors. Three claims, three figures.

28,127/08. **Wiring Conduit.** W. W. Strode. Wiring conduits for insertion in thin partition walls of concrete or hard fireproof material, are constructed of thin metal sheet. The conduit comprises a flat base and sides provided with flanges which embrace the edges of the wall slabs. The conduit is inserted during the construction of the wall. Its depth is the same as the thickness of the slabs, and a cover plate similar to the base is screwed to the front. Both base and cover are provided with recesses on their outer surface, so that they will take the plaster which is laid over the whole wall. Alternately, the conduit may be composed of two troughs back to back, with a cover on each side of the wall, and flanges on the edges to engage with the slabs. Six claims, five figures.

4,111/09. **Motor Starter.** A. H. Curtis, A. H. Mackley, and Adams Manufacturing Co., Ltd. In screw- or worm-gear operated motor-starters, a quick step-by-step motion over the contacts is obtained by combining with the rotary movement of the worm, an axial movement produced by a fixed tooth working in a helical groove in a nut fixed to the worm shaft. Five claims, five figures.

4,694/09. **Series Filament Lamps.** C. H. Stearn and C. F. Topham. It has been found that when multiple bulb series lamps, of the type described in Electrical Engineering, April 30th, 1908, p. 651, are working on low voltage circuits, the full pressure is not always sufficient to break down the insulation and complete the carbon filament circuit on failure of a metal filament. To remedy this, an arrangement is introduced to act as an induction coil, and to cause a high potential to be produced across the insulation on the interruption of the circuit by the failure of a lamp unit. Three claims, two figures.

15,786/09. **Water Heaters.** A. Ponzini. Electric geysers and other forms of liquid heaters for use on A.-C. circuits are constructed in the form of a long cylinder of iron or steel, the outer wall of which is grooved at right angles to the axis. This cylinder is surrounded by a coil which induces eddy currents in the iron. On account of the skin effect, these currents are concentrated in the annular ridges between the grooves which act as short-circuited turns of a transformer. The heat generated is transmitted through the wall of the cylinder to the liquid. Three claims, six figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Winkler [Transparent, flexible, infusible insulating material] 24,597/08; Carr and Bullers, Ltd. [Manufacture of line insulators] 3,798/09; British Insulated & Helsby Cables, Ltd., Aitken, and Sproule [Insulated cables] 4,172/09.

Dynamos, Motors, & Transformers: Stansfield and Hatt [Boosters for train-lighting systems] 16,473/08; Fessenden [High-speed motors] 21,481/08; British Thomson-Houston Co. (*General Electric Co.*) [A.-C. machines] 25,465/08; Garty [Machines] 14,391/09; Siemens Bros. Dynamo Works (*Siemens Schuckertwerke-Ges.*) [Noiseless rotors] 19,012/09; Lamme [Cooling of rotor windings] 19,392/09; Siemens Bros. Dynamo Works (*Siemens Schuckertwerke-Ges.*) [Cooling of rotor windings] 19,599/09.

Electric Ignition: Feaviour [Sparking-plug attachment] 24,525/08.

Electrometallurgy and Electrochemistry: Vollert [Electrolytic process for cleaning metal before nickelling] 27,034/08, Ruthenburg [Furnace electrodes] 4,175/09.

Heating and Cooking: Abbott [Fluid-heater] 24,038/08.

Incandescent Lamps: Soc. Francaise d'Incandescence par le Gaz (Systeme Auer) [Lamps] 24,212/08; Meszaros [Metal filament lamps] 667/09.

Instruments and Meters: Parkes [Apparatus for plotting magnetic lines of force] 6,258/09.

Storage Batteries: Traun [Cell linings] 11,116/09.

Switchgear, Fuses, and Fittings: Cardwell, Bcorman, Ford-Lloyd, Ltd., and Stirling [Switch] 25,819/08; Charles H. Pugh, Ltd., and Bull [Wiring-conduit fittings] 26,232/08; British Thomson-Houston Co. (*General Electric Co.*) [Motor controller] 28,188/08; McClelland [Lamp-holder with locking device] 299/09; Broadbent [Tool for removing lamp-shade rings] 2,730/09.

Traction: Johnson [Signalling] 24,261/08; Gresham [Vacuum brakes] 24,461/08; Electric Control, Ltd., and Macmillan [Brakes] 26,089/08; Smith [Electric block-signalling] 2,150/09; Gresham [Sanding device] 3,384/09; W. R. Sykes Interlocking Signal Co. and Sykes [Signals] 6,145/09.

Miscellaneous: Conner [Electro-magnetic counters] 4,271/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: Akt.-Ges. Brown, Boveri et Cie. [Excitation of commutator generators] 20,899/09.

Electrometallurgy, &c.: Reid [Furnaces] 6,820/09; Norsk Hydro Elektrisk Kvaelstofaktieselskab [Production of nitrate of ammonium] 25,111/09.

Instruments, &c.: Akt.-Ges. Körting's Elektricitäts-Werke [Motor meters] 12,878/09.

Switchgear, &c.: Murray [Cut-outs] 23,228/09.

Telephony: Hufschmidt and Wagner [Telephone mouth-pieces] 23,269/09.

Miscellaneous: Siemens Schuckertwerke-Ges. [Transportation of machines] 25,627/09.

Opposition to Grant of Patent

8,104/08. **Filaments of Refractory Oxides.** G. Michaud and E. Delasson. An appeal has been lodged against the decision of the Comptroller General to allow the grant of this patent. The patent, abstracted in Electrical Engineering, Nov. 18th, page 976, covers filaments of 92 per cent. thorium oxide and small percentages of other oxides. These filaments are brought to incandescence in the atmosphere.

Patent Amended

19,886/08. **Induction Coil.** H. F. Bigge and F. R. Butt. A disclaiming note has been added to this specification. The patent covers a hollow iron core for induction coils, formed by arranging the iron wires between slips of vulcanite spaced radially around a central tube of insulating material.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

23,127 of Dec. 3rd, 1895. **Magnetic Lock for Miners' Lamps.** W. Ackroyd and W. Best. An illustrated abstract of this important patent is given on page 1027 of this issue.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distribution Systems, &c.: F. G. Kleinsteuber [H.-T. insulators] 17,285/04; P. N. Hooper and A. Duckham [Conduits for bare conductors] 16,249/05.

Dynamos, &c.: British Thomson-Houston Co. (*D. P. Thompson and A. H. Armstrong, U.S.A.*) [Armature windings] 17,818/96; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Equipotential connections] 16,305/05, and [Ice-thawing generator] 16,304/05.

Electric Ignition: F. R. Simms [Sparking-plugs] 16,179/05.

Instruments and Meters: G. K. B. Elphinstone [Recording ammeters and voltmeters] 17,577/96; G. Hookham [D.-C. Mercury motor meter] 16,121/01; O. T. Bláthy [Induction motor meter] 17,685/02; Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*) [Periodic recording instruments] 17,528/04.

Switchgear, &c.: E. W. Lloyd and L. Newitt [Double-blade circular switch] 18,801/97; W. H. Scott [Circuit-breaker for drum-controllers] 17,442/04; E. Turner [H.-T. oil circuit-breaker] 16,324/05; K. Schmahl [Tumbler-switch] 16,373/05.

Telephony and Telegraphy: R. A. Fessenden [Wireless Telegraphy] 17,704-7/02; A. Orling and F. W. Corby [Electro-capilliary recorder] 16,143/05.

Traction: S. P. Thompson and M. Walker [Surface-contact system] 18,416/97; S. Savelsohn [Coach control and lighting-wire couplings] 17,431/03; E. Kramer [Electrically operated air-brake valves] 16,933/04.

Miscellaneous: R. Haddan (*A. Stigler, Milan*) [Push-button lift control] 14,488/00; W. de Friès [Crane control] 17,720/02; N. Norris [Operation of rail and overhead points] 17,632/04.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

Since the General Electric Co. placed their 32-watt 200-volt Osram lamp on the market, over half a million lamps have been sold. The company and their agents have been rather behindhand in deliveries both of this size and other sizes recently, but an improvement in this respect may be expected. (Page 1033.)

At the adjourned inquest upon the motorman and conductor who were killed in the accident to a District Railway train at Ealing Broadway station on November 18th, the jury returned a verdict of accidental death due to the failure of the brakes to act, but added that there had been general slackness in the examination of the brakes. It appeared from the evidence that, contrary to regulations, neither the motorman nor the conductor inspected the air-brakes, and that, as a matter of fact, there had been no air in the reservoir or train-pipe. (Page 1033.)

Some additional information is available concerning the recent arc lamp patent action in Germany, to which a short article was devoted in our last issue. It appears that the patent which has been revoked is not the fundamental Beck patent. (Page 1033.)

The Associated Municipal Electrical Engineers of Greater London propose the appointment of a Joint Committee of local authorities and companies for publishing literature relating to electricity supply. (Page 1033.)

In a single-battery train-lighting system developed by the Tudor Accumulator Co., the dynamo is spring suspended, and belt-driven from a coach axle. The machine cuts in at 300 r.p.m., and the voltage is kept down with rising speed by an opposing series field. An automatic switch reduces the shunt excitation when the battery is fully charged, and the lamp pressure is kept constant within 4 per cent. by means of iron-wire series resistances. Fifteen cells are required, the lamp pressure being 24 volts. (Page 1034.)

An illustrated article deals with the advantages of the bow system over the trolley system of collection for tramcars. (Page 1035.)

An article on shop-window and shop lighting reviews the present tendencies in this direction, and gives illustrations of some fittings made by a leading firm. (Page 1037.)

A simple design of circuit-breaker is described. One coil serves as both overload and blow-out magnet, and carries the whole current. There are no springs and remarkably few working parts. A fuse in the body of the switch is in series with the main contacts. (Page 1038.)

Digitized by Google

A DESCRIPTION is given of a recording device for showing when lightning arrestors and other protective spark gaps have been in action, which is in use on the Heysham-Morecambe section of the Midland Railway. (Page 1039.)

AN improved design of dust-proof semi-indirect lighting fitting, and some new patterns of portable battery lamps, are described on page 1040.

WE have received a letter from Mr. P. J. Pringle, referring to the article on danger from live trolley standards published in our issue of November 25th.—A letter from the Secretary of the Bradford Engineering Society repudiates the suggestion that the recently published report on electric drving of textile factories was published without the knowledge of all the members of the committee whose views it is intended to embody. (Page 1040.)

SOME extracts from the regulations for carrying on wireless telegraphy between ships, and from ship to shore, are given on page 1041.

A 116-TON goods locomotive of a new design has just been constructed for the New York, New Haven, & Hartford Railroad. It has two trucks, each with four driving wheels, and one pair of leading wheels. An intermediate bar between the trucks takes the whole tractive effort of the leading truck, and a special construction gives one truck a backwards and forwards, as well as a rotary, motion. The four 350 h.p. compensated series commutator motors can be supplied from the 600-volt third-rail, or from the 11,000-volt 25-cycle overhead wire. Arrangements for controlling two such locomotives from a single master controller are also provided. (Page 1041.)

ALL tramway centre poles in Belfast are to be removed to the footpaths.—A Committee of the Bradford Corporation is inspecting trolley omnibus systems on the Continent.—Falmouth Council propose to apply for powers to use the trolley omnibus.—Arrangements are to be made at Brighton for contractors to wire consumers' premises, and for the Corporation to charge one penny per unit extra for supply.—A scheme for converting the Isle of Wight railways to electric traction is under consideration.—The Electrical Contractors' Association will oppose the Middlesbrough Corporation's application for wiring powers, unless the work is carried out through a contractor. (Page 1042.)

GENERATING plant is required by the Belfast Corporation and Govan Corporation. Condensing plant is required at Eastbourne, and coal-handling plant at Stepney. Mains are to be extended at Islington and Stepney. Electrical extensions are proposed at York and Walsall. (Page 1044.)

A NET profit of £57,927 is shown by the accounts of the India Rubber Gutta-Percha & Telegraph Works Co. The loss to date on the working of the Electromobile Co. amounts to £6,511. (Page 1045.)

MR. F. H. R. Lavender read a Paper last week before the Birmingham Local Section of the Institution of Electrical Engineers containing the results of a long series of tests of metal filament lamps, undertaken in order to investigate the conditions of working as regards voltage, and efficiency and percentage drop in candle-power, giving the most economical life in the case of metal filament glow lamps, and to determine as far as possible the cost of illumination with this source of light. (Page 1047.)

A PAPER read by Prof. E. W. Marchant and Mr. E. A. Watson before the Manchester Local Section of the Institution of Electrical Engineers considered the principal features of high-tension transmission as carried out in modern plants in America, and in the discussion the applicability or otherwise of some of the methods described to this country was considered. (Page 1049.)

A VERY successful annual dinner was held by the Glasgow Local Section of the Institution of Electrical Engineers last week. (Page 1051.)

AMONG the specifications published by the Patent Office on Thursday was one by the Société Française d'Incandescence par le Gaz for supports for metal filaments, comprising nickel wires arranged in a helix with fine platinum hooks at their ends.—A method of supporting silvered glass reflectors inside the filament cages of metal-filament lamps is protected by J. Meszaros, and a tool for removing lamp-shade rings is described by D. L. Broadbent.—The British Insulated & Helsby Cables, Ltd., have a specification for a telephone cable for use in switchboard construction, and a method of lessening the noise produced by rotors with salient poles is protected by Siemens Bros. Dynamo Works, Ltd.—Opposition has been entered to the grant of two patents. The first, by the Glühlampenwerk Anker Ges., relates to the introduction of phosphorus in metal filament lamp bulbs to reduce blackening, and the other, by Brown, Boveri & Cie., covers a flywheel load-equalising system. (Page 1052.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, DECEMBER 9TH.

Institution of Electrical Engineers.

8 p.m. At 25 Great George Street, London. "Notes on Methods and Practice in the German Electrical Industry," by L. J. Lepine and A. R. Stelling.

Institution of Electrical Engineers: Dublin Section.

8 p.m. At Royal College of Science. "The Tierney-Malone Point Shifting Device as used on Dublin and other Tramways," by T. P. Tierney.

FRIDAY, DECEMBER 10TH.

Northampton Institute.

6.30—11 p.m. Conversazione and prize distribution.

SATURDAY, DECEMBER 11TH.

Mining Institute of Scotland.

2.45 p.m. At 18 George Street, Edinburgh. Mr. John Paul's Paper:—"Electrical Power Generation and Distribution at the Collieries of the Lochgelly Iron and Coal Co.," will be discussed.

Northampton Institute.

6.30—11 p.m. Conversazione.

Birmingham and District Electric Club.

7 p.m. Annual meeting at Colonnade Hotel, New Street.

MONDAY, DECEMBER 13TH.

Institution of Electrical Engineers: Newcastle Section.

8 p.m. At Armstrong College. "On the Use of the Flicker Photometer for Differently Coloured Lights," by H. Morris Airey.

TUESDAY, DECEMBER 14TH.

National Electrical Manufacturers' Association.

2.30 p.m. Committee meeting at Balfour House, Finsbury Pavement, E.C.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. At the University. "Notes on Methods and Practice in the German Electrical Industry," by L. J. Lepine and A. R. Stelling.

Institution of Electrical Engineers: Glasgow Section.

8 p.m. At 207 Bath Street.

Physical Society.

3—6 p.m. and 7—10 p.m. Annual Exhibition at Imperial College of Science, South Kensington.

WEDNESDAY, DECEMBER 15TH.

Institution of Electrical Engineers: Leeds Section.

7.15 p.m. At the University. "Metallic Filament Lamps, their Possible Beneficial Effects on Supply Undertakings," by G. Wilkinson and R. McCourt.

Dynamicables.

7 for 7.30 p.m. Dinner at the Trocadero Restaurant.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. At 92 Victoria Street, London. "Electricity Supply on Tap," by C. B. Nadaud and W. Bernard Thompson.

THURSDAY, DECEMBER 16TH.

Institution of Electrical Engineers.

8 p.m. At 25 Great George Street, Westminster. (1) "Some Quantitative Measurements in Connection with Radiotelegraphy," by Dr. J. A. Fleming, F.R.S. (2) "Efficiency of Short Spark Methods of Generating Electrical Oscillations," by Dr. W. H. Eccles and A. J. Makower.

FRIDAY, DECEMBER 17TH.

Electro-Harmonic Society.

8 p.m. Smoking Concert at Holborn Restaurant.

DELIVERIES OF OSRAM LAMPS

DURING the last few weeks there has been such a demand for 200-volt Osram lamps that there has been some difficulty in getting deliveries of some sizes both from the General Electric Company and their agents. We understand, however, that a considerable improvement may now be expected in this respect.

Since the Company put their 32-watt 200-volt Osram lamp on the market last June over half a million lamps have been sold. The Company had made arrangements with both the English and Continental factories that the deliveries they should receive would be more than double last year's deliveries, but the demand has somewhat exceeded even this great supply. It will be readily understood that it was a demand somewhat difficult to forecast, for although the approximate replacement of carbon filament lamps in the United Kingdom could be estimated and the stock arrangements for metal filament lamps made at the speed at which the replacement of carbon lamps would be required, yet it was almost impossible to gauge the rate at which electricity would supplant gas-lighting, and the Company believes that it is in this direction that the extraordinary increase in the demand for Osram lamps over their estimates is to be accounted for.

THE COLLISION AT EALING ON THE DISTRICT RAILWAY

AT the Ealing Town Hall, on Thursday, Mr. Reginald Kemp held the adjourned inquest concerning the deaths of the motor-man and conductor, who were killed at Ealing Broadway Station of the District Railway on November 18th. It will be remembered that an empty train, entering the station, ran into the buffers of the platform, completely wrecking the two front coaches and doing considerable damage to the station. The mystery, however, was cleared up at the adjourned inquest, when the jury returned a verdict of accidental death due to the failure of the brakes to act, but added a rider to the effect that there had been general slackness in inspecting the brakes of the train in question.

On the morning of the accident the train left the Ealing Common depôt at 5.31½ a.m., instead of 5.33 a.m. It is the duty of the two conductors and the driver to test the brakes before leaving the depôt, but it was given in evidence by the conductor who was at the rear of the train that he had not, on the particular morning, carried out this duty, and that, so far as he was aware, neither had the dead motor-man or the dead conductor. Subsequent evidence made it perfectly clear that no testing of the Westinghouse brakes had taken place, for after the collision the isolating cock in the motor-man's cabin was found turned off, *i.e.*, in the position in which it was left on the sidings the previous night. What took place, therefore, can be summed up very briefly. The train left the depôt without any air in the air reservoirs or train pipe, although a glance, on the part of the motor-man, at the pressure gauge, which is placed practically on a level with his face, would have shown this. The rule of the company is that the driver of a train must apply his Westinghouse brake before the home signal at Ealing Broadway station. Apparently this was done with, of course, no effect. The motor-man immediately attempted to reverse the current, which would probably have averted the accident had it been carried out intelligently. The regulations of the company prescribe that when this is resorted to, the controller should be put over to the second notch, and then worked back gradually in order to avoid any risk of the circuit breakers blowing out. Examination of the motor coach, however, showed that instead of stopping at the second notch, after reversing, the motor-man had put the main handle right over. Consequently, the sub-station circuit breakers came out, thus rendering that section of the line dead, in addition to putting the train, the signal cabins, and the station into darkness. It was now too late to check the speed of the train, which was estimated at from 10 to 15 miles per hour, by the hand-brake, and the train crashed into the buffers as mentioned above, with, unfortunately, fatal results.

Subsequent examination and tests proved that the Westinghouse brake gear was in perfect working order, but that on the particular morning there had never been any air in the system, and that they had not been applied during the run from the depôt to Ealing Broadway station. Mr. W. A. Agnew, the railway company's mechanical engineer, was completely satisfied that the accident could not have occurred had the regulations been followed. Major Pringle, of the Board of Trade, who was present at the inquest, will report, as usual, in due course.

ARC LAMP PATENT ACTION IN GERMANY

WE are able to publish some interesting additional information in connection with the short article under this heading in our last issue. The German patent that has been revoked is No. 185,758, of 1906, of the Deutsche Beck-Bogenlampen-Gesellschaft [in the information sent us and published in our last issue, the number was erroneously given as No. 186,758]. This patent is not the fundamental one which governs the manufacture of the Beck lamp. In the fundamental patent (British patent No. 16,294 of 1903), a method of supporting one or both carbons from below in a gravity-feed lamp is described, and is summarised as follows in the first of the sixteen claims of the patent :—

"In electric arc lamps the method of controlling the feeding of the electrodes by providing one or both of them with a longitudinal ridge of carbon or similar material which rests upon a supporting surface, and is gradually consumed in the heat of the arc, whereby the electrodes descend under the influence of gravity and maintain the arc of practically constant length substantially as described."

The German patent which has been revoked describes a particular arrangement in which the *negative* carbon is supported, and the following is the translation of its claim :—

"An arrangement of the electrodes in continuous-current arc lamps of the type in which the carbons are supported side-by-side from below, distinguished by the fact that only the negative carbon (containing little or no metallic salts) is provided with a supporting ridge and rests on a support, in order that a satisfactory distribution of the light from the positive crater may be obtained."

We have reason to believe that the later German patent was revoked on account of it having been anticipated by the 1903 patent which we have mentioned above, and on a comparison of the two claims the decision does not seem to be surprising, for the claim which we have quoted from the fundamental Beck patent certainly seems to cover the arrangement described in the later one.

An examination of the two patents reveals the fact that, under the original patent, preference was given to the positive carbon being supported rather than the negative, while the later patent apparently describes a construction suitable rather for ordinary arcs than flame arcs.

ADVERTISING ELECTRICITY IN LONDON

THE Associated Municipal Electrical Engineers of Greater London have proposed the appointment of a Joint Committee consisting of fourteen members (seven being selected from the chief officials of the municipal undertakings and seven from the chief officials of the London companies) to have the title of "The Electric Supply Publicity Committee of London and District." The committee, it is suggested, should hold regular meetings for discussing the organisation and administration of publicity matters in relation to electricity supply, and the preparation, printing, and publication of publicity productions of common interest. In the first instance, the work of the committee would be confined to members of the association, but such an organisation could not, it is felt, be set up unless some support is assured. It is therefore proposed that for the first year orders for publishing work to the value of about £1,000 should be guaranteed by the various undertakings, and in order that the committee may have funds to commence operations, it is suggested that each local authority or company joining the organisation shall in the first instance subscribe on the following basis :—Gross revenue of undertakings from private supply, not exceeding £10,000, minimum annual contribution, £10; not exceeding £20,000, £20; not exceeding £30,000, £30; not exceeding £40,000, £40; not exceeding £75,000, £50; exceeding £75,000, £60. The methods of publicity will consist of :—(1) Publicity of leaflets, cards, posters, &c.; (2) regular issue of short leaflets; (3) preparation of pamphlets on power, light, new methods of electric lighting, residential lighting, shop lighting, heating, and cooking, types of heaters, cooking apparatus, economy in use, &c. It is expected that the production of pamphlets on a large scale will so reduce the cost that undertakings will obtain very much more advertising matter, than is possible by any other means.

Meeting of London Supply Engineers.—A special meeting of representatives of the Associated Municipal Electrical Engineers of Greater London and the London Companies' Officials Association was held at the Hammersmith Electricity Works on Dec. 2nd. Papers were read by Mr. A. H. Seabrook on "The Telephone System of Charging," and by Mr. G. G. Bell on "Electric Heating with Special Reference to the Therol Heater." The meeting was largely attended by representatives of both associations, and an interesting discussion took place. It is hoped that future meetings of a similar nature will be arranged.

THE T.A.C. TRAIN-LIGHTING SYSTEM

THE Tudor Accumulator Co., Ltd. (119 Victoria Street, London, S.W.) have developed a system of train-lighting in which a single battery works in parallel with a dynamo driven from the carriage axle. This dynamo is differentially wound, the series-winding reducing the main magnetic flux when the speed rises. The machine cuts in at 300 r.p.m., and the test curve shows that at a speed of 500 r.p.m. a current of nearly 40 amperes is delivered; the rise after this is so slight that at a speed of 2,800 r.p.m. the current does not exceed 53 amperes. Diverters are shunted across the series-winding, and the output can be adjusted to the desired value by altering these. Further adjustment is possible in the shunt field circuit. The brush rocker is mounted on ball-bearings, and if the direction of rotation is altered, the brushes automatically shift round a pole pitch so as to keep the polarity the same. Commutation is stated to be perfect even at such a high speed as 2,600 r.p.m. The four cables from the machine are run in a 1-in. flexible tube to a four-pole terminal box under the coach. Fig. 1 shows the method of suspending and driving the dynamo which could, however, be equally well suspended direct on the bogie frame of a bogie coach.

The connections are illustrated in Fig. 2. The automatic switch *A* has both shunt and series coils. When the speed

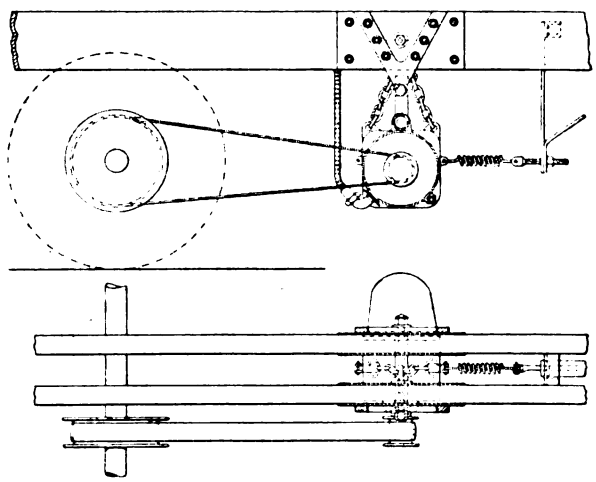

FIG. 1.—SKETCH SHOWING SUSPENSION AND DRIVE OF DYNAMO.

is such that the normal voltage is reached, the shunt coil closes the switch and connects the dynamo to the battery; and as long as the dynamo is generating, the series coil keeps the switch closed. As the dynamo slows up, however, the voltage across its brushes drops until it is slightly below that of the battery, a reverse current then flows through the series coil, and as soon as it rises to two or three amperes, the switch opens. In order to prevent overcharging or running-down, it is necessary to employ an overcharge switch *B*, which is set to open as soon as the battery becomes fully charged, and not to close again until the dynamo comes nearly to rest. When the switch is closed its armature connects three or more contacts, according to the number of lamp or other circuits to be controlled, and when open disconnects them, and increases the resistance in series with the field circuit, reducing the output of the dynamo to suit the load in circuit.

The working of the system is as follows:—With the coach at rest, the lamps are supplied from the battery, and as there is no voltage across the dynamo brushes, the switches *A* and *B* will be in the open and closed positions respectively. As the coach starts, the brush rocker will move into the position, the machine will excite, and the field current pass from the — brush through the shunt field winding to the two groups of iron-wire resistances *R P* (which allow a definite current to pass, independent of a large voltage fluctuation); here it splits up and a definite portion passes to the terminals 1 and 2 of the switch *B*, and thence to terminal 3, and through the resistance *K* to the + brush. As soon as the machine attains a speed of 300 r.p.m. it generates the necessary voltage and the main switch *A* closes; as the speed further increases, the output rises, and when the current exceeds the lamp load the excess goes to charge the battery. When the battery voltage attains the full charge value, the switch *B* breaks circuit at the terminals 1, 2, and 3, so that the resistances *P* are cut out. This decreases the field current, and the dynamo output is reduced to the lamp load, the remaining field current being that flowing through resistances *R* and *M* and switch *S*.

If now the main lamp switch *S* is opened, the field current is reduced to a very small value, namely that which passes through the group of resistances *R, M, N,* and *K*. This small field current is just sufficient to make the dynamo give two or three amperes at high speeds, and serves to top up the battery and prevent switches *A* and *B* hunting. As the dynamo slows up, the output gradually falls, switch *A* opens, and when it comes nearly to rest, *B* closes. For the sake of simplicity only one lamp circuit has been assumed, but as many as desired may be interconnected with field and overcharge switch.

The lamps *L* are permanently connected across the battery, and are run in series with iron-wire resistances *Z*, which absorb the fluctuations due to the battery either being on charge or discharge. In practice the lamp voltage remains constant within 4 per cent. In order to maintain a lamp pressure of 24 volts, fifteen cells are employed where otherwise only thirteen would be necessary. It is stated, however, that the loss is not serious, and that the simplification which the resistances effect over any mechanical regulator more than justifies their use. Their life is long and the cost of renewal small. Tudor cells, especially designed for train-lighting work, are employed.

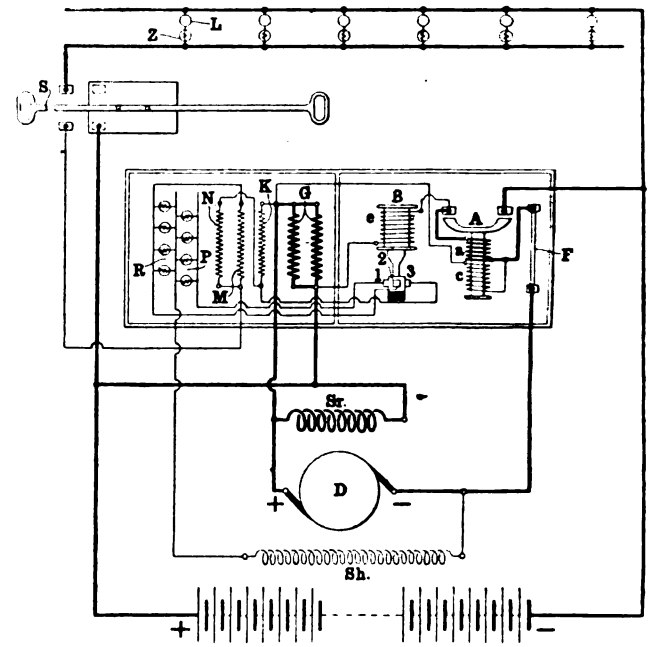

FIG. 2.—DIAGRAM OF CONNECTIONS.

The positive plates are of the Planté formation, and the cells are contained in teak boxes with acid-tight lids. Holding-down bolts, terminal bolts and connectors are heavily lead-plated to avoid corrosion.

The advantages claimed for the T.A.C. system are:—(1) extremely good voltage regulation; (2) long life and low maintenance cost of the battery; (3) simplicity of the dynamo; (4) small amount of automatic switchgear; (5) simplicity of the wiring; and (6) low total maintenance costs. Special stress is laid on the fact that it is a single-battery system, it being stated that it is impossible in the two-battery system to avoid heavy strains on the batteries due to one charging while the other is discharging. The Tudor Co. also quote a long list of railways on the Continent and elsewhere which use iron-wire lamp resistances. They are said to be giving complete satisfaction in all cases.

Obituary.—We regret to announce the death, on Saturday last, from pneumonia following influenza, of Mr. S. Charlesworth, who had been for some time secretarial assistant to Mr. S. L. Pearce, Chief Electrical Engineer to the Manchester Corporation. Mr. Charlesworth was also well known to members of the Manchester local section of the Institution of Electrical Engineers, where he acted as official reporter at the discussions.

Electric Smelting.—A company is to be formed, says the *Standard*, under the name of the Electric Steel Co. of Canada, Ltd., for the establishment of an electric smelting plant, at Welland, in the Niagara Peninsula. A contract has been entered into with the Niagara Falls Power Co. for the supply of electrical energy amounting to 1,000 h.p., and the construction of the first mill has been commenced. It is estimated that the daily output will be 1,000 tons, which will require 2,000 tons of ore daily. It is further stated that five vessels have already been secured to deliver ores before the close of navigation.

BOW COLLECTORS FOR TRAMCARS

THE question which of the two types of current collectors for electric vehicles, trolley wheel or bow, is the most advantageous for tramway purposes, has given rise to a good deal of discussion from time to time, and the case for the bow contact, as set forth in a communication which we have received from Mr. A. Schmit (of Messrs. Siemens Brothers Dynamo Works, Ltd.) is of considerable interest. Mr. Schmit asserts that the cost of maintenance of the bow is about the same as that of the trolley wheel, and that the wear on the trolley wire

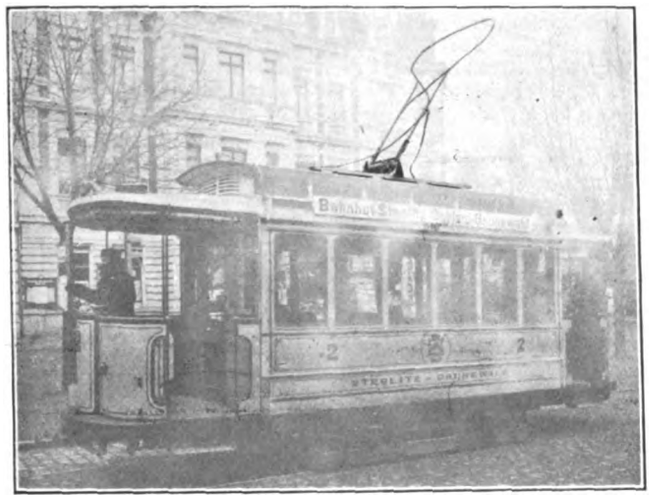

FIG. 1.—SINGLE-DECKED CAR WITH STANDARD FIXED-AXLE BOW COLLECTOR.

due to the trolley wheel is greater than that due to the sliding contact, and proceeds to a consideration of various advantages claimed over the trolley.

Almost the only applications of the bow collector in this country up to the present are for shunting locomotives and high-speed trains on main lines, where the trolley would be out of the question. For tramway work, however, there is, as far as we know, no other English example of the use of the bow than the Sheerness tramways, where, however, on account of special conditions, the full advantages of the system cannot be realised.

One of the most important advantages claimed for the bow contact is that if the line is properly erected, the collector cannot leave the trolley wire and wreck the overhead line. This is of importance on sharp curves and on down gradients, as it

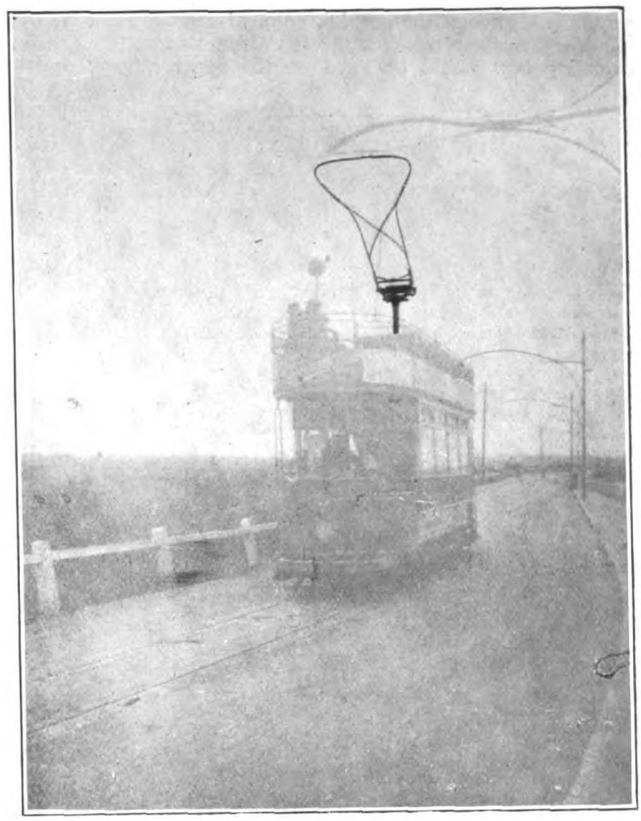

FIG. 2.—SWIVELLING BOW ON COLUMN, DOUBLE-DECKED CAR. (SHEERNESS TRAMWAYS.)

increases the security of the line and releases the conductor from the troublesome business of supervising the trolley pole when the car passes round curves. The automatic reversibility of the bow collector when the car changes direction, also gives the conductor a longer rest at the terminus and enables the car to be ready sooner for a fresh start.

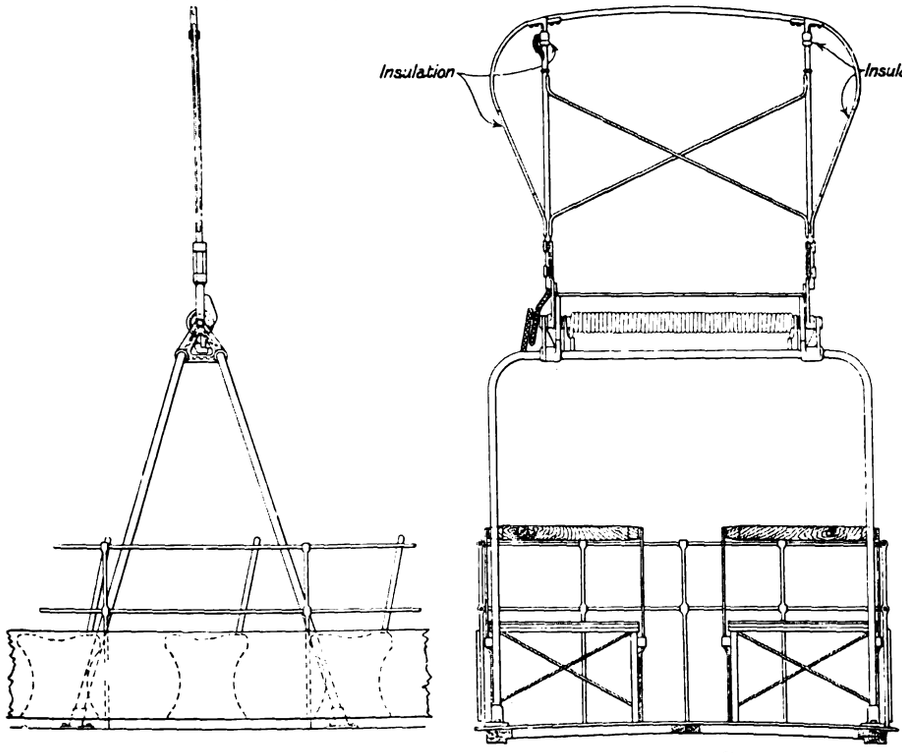

FIG. 3.—REVERSING BOW COLLECTOR FOR DOUBLE-DECKED CAR.

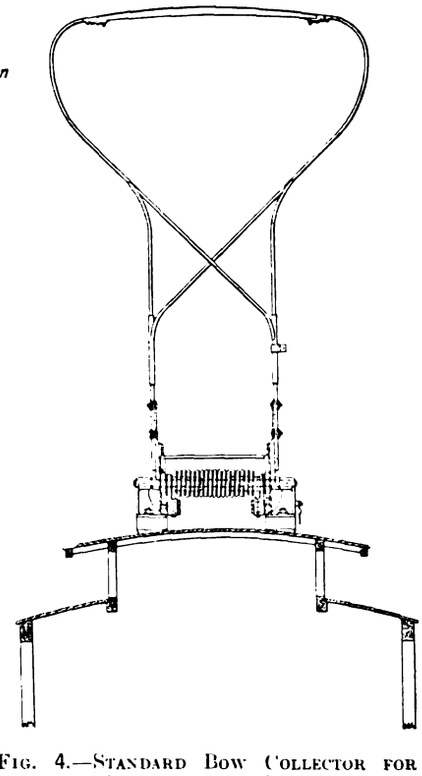

FIG. 4.—STANDARD BOW COLLECTOR FOR SINGLE-DECKED CAR.

Digitized by Google

On single-deck cars the ordinary bow type, illustrated in Figs. 1 and 4, as used on the Continent, is the most suitable, either with fixed axle or with suspended axle. The suspended axle is specially adapted to cases in which cars have to change their direction of running at places where no provision was made for this purpose when the line was laid out. When the cars only change at the termini, bows with fixed axles are quite reliable. On double-deck cars with covered upper deck, a self-reversing bow would be fixed on the upper canopy, or on a special construction fixed to each of the side walls of the upper parts of the car if the canopy is not strong enough. On a double-deck car without a top cover the bow would have to be carried on a column or standard, as in Fig. 2. A better method of support is by means of the arch arrangement shown in Fig. 3, which gives more room; the sliding contact strips would in these instances be insulated from the main frame.

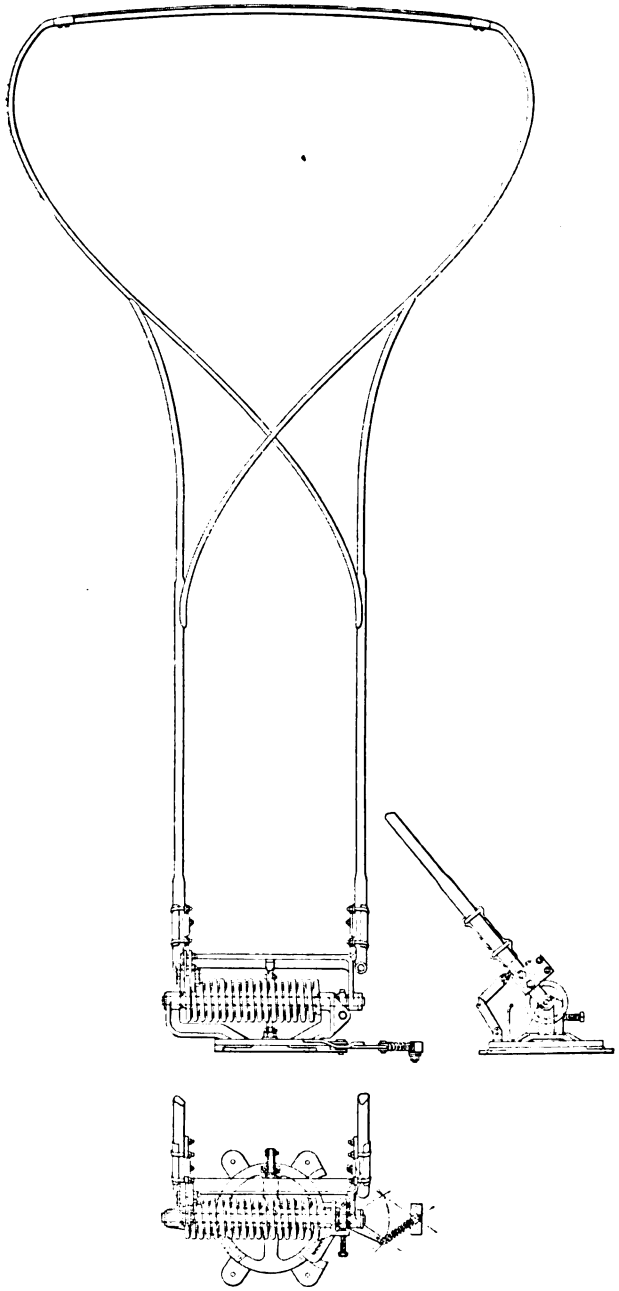

Fig. 5.—Swivelling Bow Collector.

In cases where a self-reversing bow is not suitable, the bow can either be arranged as a swivelling trolley, to be turned round at each terminus, as shows in Figs. 2 and 5, or with an upper bow. The latter arrangement, which is, however, more used on locomotives and railways, would enable the car to change its direction at any time, and the upper bow would automatically turn over and act as a trailing bow, the main frame remaining in its original position, facing the direction of motion. A similar arrangement has been adopted successfully for speeds up to 65-70 miles per hour.

For ordinary tramways all cases can thus be met without going to the expense of the pantograph construction, but for high speeds and cases where great variations in height have to be met, the pantograph is more convenient on account of its better balance.

The bow contact enables simpler arrangements to be used, and gives neater appearance to the overhead line on curves, with a smaller number of puff-offs. There is no necessity for special frogs or crossings, as the trolley wires are fixed on special hangers, so that the bow can pass smoothly from one wire to the other It is also claimed that for an equal maintenance cost of the current collector there is less wear on the trolley wire. For ordinary tramway work, with currents up to 100 amperes, a single bow is quite sufficient. Where more current per car is required, a double bow may be used, or a single bow frame with two upper swivelling bows attached to it.

The actual contact strips are of aluminium with a U or a W section, according to the current to be collected, the longitudinal grooves being filled with grease. The strips are slightly curved with upward convexity, so as to enable them to pass the points of support of the overhead wire without danger of fouling the hangers or span wires. In many English towns an objection might be raised to any alteration from the trolley to the bow system on account of a through service of cars from other tramways. This need not, however, be an insuperable objection in cases where the overlapping of the two systems is not extensive, inasmuch as special frogs and crossings and special fittings have been designed for common use by the trolley wheel and the bow. In certain Continental towns these special fittings have been installed, and no serious difficulties have been experienced.

Mr. Schmit gives the following information and statistics as thoroughly representative of the wear experienced :—One million trolley wheels passing a certain point of a trolley wire of 53 sq. mm. = No. O B & S. cross-section will wear away of that cross-section between points of suspension from 12 per cent. to 20 per cent. One million bows will wear away 3–20 per cent. The difference between a well-maintained line and a poorly maintained line is much higher for the bow system than for the ordinary trolley-wheel system, the bow being more sensitive upon bad service than the wheel. At the points of suspension the wear will be higher, and is about 1·4–1·9 times as high as between points of suspension with wheel system, as compared with 1·7–1·2 times with the bow system. In curves and at frogs, section insulators, &c., the wear is about 1·5–2·2 times as high as between points of suspension with wheel system, as compared with 3–2 with the bow system, the latter figures referring to poorly maintained lines. Although with the bow system the wear of the trolley wire in curves is 3 times as high as on straight line track, it is much lower than with the wheel system, the figures to be compared being 3×3 per cent. = 9 per cent., and 1·5×12 per cent. = 18 per cent. of the original cross-section of the wire. On poorly maintained lines these figures would be 2·2×20 per cent. = 44 per cent. for the wheel system, and 2×20 per cent. = 40 per cent. for the bow system. The wear of the wire on curves is naturally highest at the points of suspension.

To increase the life of the trolley wire Messrs. Siemens therefore use auxiliary wires, soldered, or preferably clamped, to the trolley wire, and protecting the latter against wear at all points where the wear would otherwise be especially high.

Other means of increasing the life of a trolley wire are :—To stagger the trolley wire from side to side so that the sliding surface of the bow may always remain smooth; to strain the wire as tight as possible in order to prevent it catching in the grooves of the aluminium collector strips, which may be formed if the collectors are not carefully looked after.

The annual cost of maintenance and repairs of an overhead line is given as about 2–4 per cent. of the initial cost; the cost for maintenance of the current collectors differs greatly, and varies between £16 6s. and £176 8s. for wheel collectors, and between £16 and £181 6s. for bow collectors, calculated on the basis of 1 million car-kilometres (about 625,000 car-miles).

Stealing Osram Lamps.—At the Mansion House last week two men, named A. J. Page and F. A. Clark, residing at Edmonton, were sentenced to three months' imprisonment with hard labour for stealing a quantity of Osram lamps from the General Electric Co., Queen Victoria Street, London, of the value of £17 15s. 7d. It appears that the prisoners induced a youth working at the General Electric Co.'s premises to secure the lamps for them without entering them out or taking any money for them.

German Society of Consulting Electrical Engineers.—A society has been formed in Berlin under the name of the Verein beratender Ingenieure für Elektrotechnik by a number of independent consulting electrical engineers. The membership is now over thirty, and includes many well-known German consulting engineers.

PROGRESS IN SHOP AND WINDOW LIGHTING

THE General Electric Co., Ltd., have sent us an interesting review of the progress that has recently been made in shop window lighting, with particular reference to their lamps and fittings. In nearly every retail business to-day one of the most potent influences for trade is the shop window. More than ever before does the British public estimate a firm's standing and the character of its productions by the way in which these latter are exhibited in the street windows. It therefore follows that so great an asset should be most carefully dealt with, and, whatever the quality and price of the goods displayed, one of the first essentials to obtaining successful results lies in displaying the goods and consequently lighting the windows in the most effective manner.

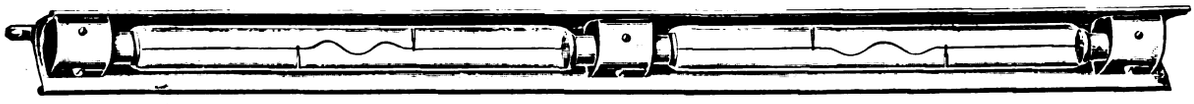

FIG. 1.—THE "STRIP-LITE" TUBULAR LAMPS.

Window lighting has made enormous strides within the past few years. While in the early days the smaller premises were lighted by incandescent lamps, the larger shops and warehouses favoured arc lamps, and these for window illumination were originally placed outside, overhanging by about eight or ten feet the street and pavements. At that time this method of lighting proved an attractive advertisement for the premises. With a view to eliminating the glare and trying effect of naked arc lamps, the method was afterwards largely adopted of shading the lamps on the street side and directing the rays through the window. This naturally led to investigations as to the best method of lighting window exhibits from the inside, and the result was that carbon filament incandescent lamps came to be used with single reflectors throwing the light on to the goods exhibited on the inside of window frames in lines, and in many cases the straight line tubular double-ended lamps (see Fig. 1) were favoured, to be followed later by the simpler and less costly method of lighting by trough reflectors such as are illustrated in Fig. 2.

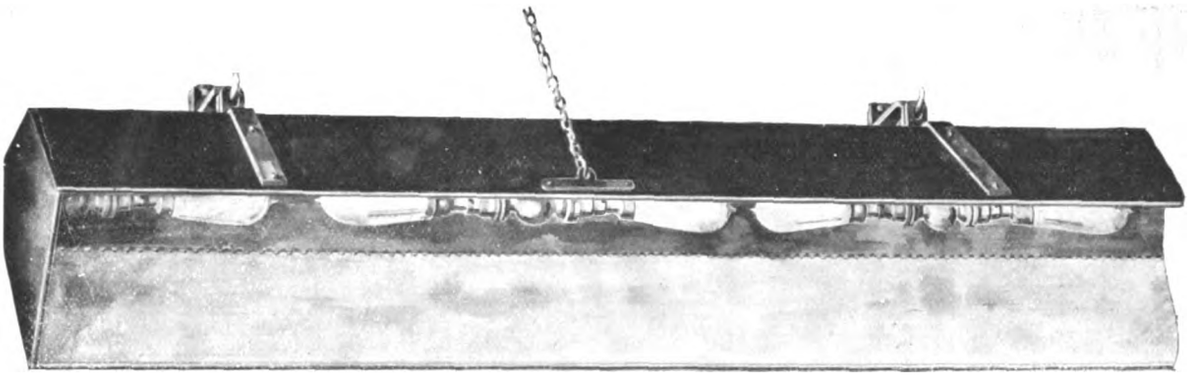

FIG. 2.—TROUGH REFLECTORS MANUFACTURED BY THE GENERAL ELECTRIC CO., LTD.

This system of lighting shop windows in troughs with Osram lamps is undoubtedly one of the most economical and effective systems in use to-day. An ideal installation on these lines is that of Selfridge's store, where twenty-one windows are illuminated in this way. The goods stand out clearly and distinctly, with only sufficient shadows to give a measure of relief to the goods exhibited, and no lamps can be seen from the outside of the windows.

For interior shop lighting, there is no doubt whatever that the Osram lamp is also making phenomenal progress. The large lantern with a group of lamps of large candle-power in a spherical globe is well known, and is now obtainable in sizes up to 1,000 c.p.

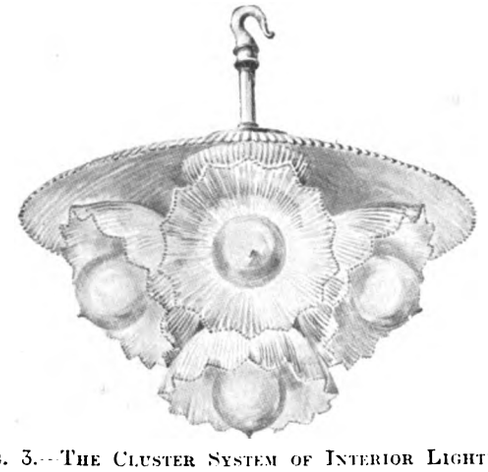

FIG. 3.—THE CLUSTER SYSTEM OF INTERIOR LIGHTING.

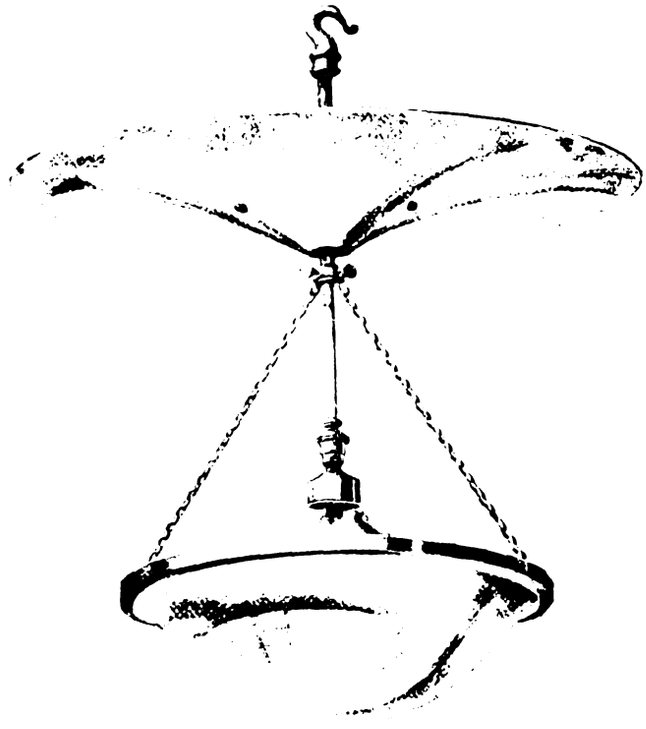
In the Army and Navy Stores and other premises the cluster system of direct lighting, as shown in Fig. 3, has been adopted in some departments with success, while, on the other hand, a more general use in the future will undoubtedly be made of inverted light fittings of similar patterns to that illustrated in Fig. 4. This system of lighting gives a soft direct light, in addition to a widely diffused reflected light, and there is an entire absence of glare or shadow, making the light restful to the eyes and easy to work under for very long periods.



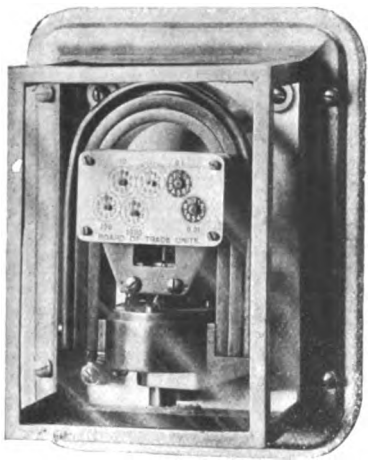


FIG. 4.—INDIRECT LIGHTING FITTING.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

AMPERE-HOUR METER.—A leaflet from the British Thomson-Houston Co., Ltd. (83 Cannon Street, London, E.C.) gives prices and particulars of a switchboard pattern of the new continuous-current ampere-hour meter described in Electrical Engineering, February 18th, 1909, p. 157. This meter is of the type in which a copper cup immersed in mercury rotates in the field of a permanent magnet. In the switchboard pattern illustrated in the accompanying figure, the meter itself is mounted on a marble base, and enclosed in a glass case. The shunt is external to the case. Either clock or cyclometer dials can be obtained, and the listed capacities range from 25 to 6,000 amperes, at any pressure up to 600 volts.

B.T.-H. Mercury Motor Meter (Switchboard Pattern).

TANTALUM LAMPS.—The latest of the series of "satisfied consumer" tantalum lamp showcards in the French design, reproduced herewith. Instead of the making of his usual remarks

French Tantalum Lamp Showcard.

as to the halving of his electric lighting bill, the gentleman is reading his morning paper by the excellent light of a tantalum lamp, which he challenges the strike leader Pataud to extinguish if he can.

CENTRAL STATION ADVERTISING. Mr. W. A. Vignoles, Borough Electrical Engineer, Grimsby, has sent us copies of two designs for enamelled iron plates for advertising purposes. One of these, bearing the inscription, "Electric power used here," is for fixing to works where motors are in use, and the other, with a representation of a metal filament lamp, announces that 16 hours' light can be obtained for one penny, and is to be fixed to lamp-posts in the town. This will probably be arranged on a bracket, and backed by a design for power similar to the one used for fixing to works, but with the wording slightly altered to suit.

OIL SWITCHES. A pamphlet received from the Electrical Co., Ltd. (121-5 Charing Cross Road, London, W.C.), describes several types of oil switches for A.C. pressures up to 1,000 volts. These switches are of the controller form, with quick make and break action. Those for 50 amperes and under are fitted with handles, while those of larger capacity (up to 200 or 400 amperes, according to the type) have hand-wheels. Designs both for erection on iron stands or on cable brackets are listed. If desired, the cases can be provided with an interlocking device.

FLAME ARC LAMPS.—A descriptive price list is to hand from Mr. G. Braulik (8 Lambeth Hill, Queen Victoria Street, E.C.).

"THEROL" CALENDAR.—A wall calendar for 1910 from Messrs. Spagnoletti & Co. (Goldhawk Road, Shepherd's Bush) illustrates various domestic and other applications of electricity which may be expected to become available at competitive prices if the "Therol" system of improving the load factor by using the supply for water heating be adopted. This system was described in Electrical Engineering, September 9th, p. 795.

THE I.C.S. STUDENT.—The November number of the magazine of International Correspondence Schools, Ltd., contains several articles emphasising the influence of technical education upon national and individual progress. The doings of I.C.S. students in various parts of the country are chronicled, and results of competitions are given.

SMALL MOTORS.—A list from the Adnil Electric Co., Ltd. (Adnil Building, Artillery Lane, E.C.), describes a line of small continuous-current motors ranging from 1/16 to 6 h.p., which have recently been brought out by the Bergmann works. These can be supplied in the open, ventilated, and enclosed patterns, as motors or dynamos. A very complete series of accessories is listed, and we understand that a large stock is held in London.

TELEPHONE SWITCHBOARDS.—Messrs. Siemens Bros. & Co., Ltd. (Caxton House, Westminster), have issued a new catalogue (No. 519) of telephone switchboards. It includes a large range of patterns and sizes, from the small wall type with drop indicators to large standard boards for private branch exchanges. The company express their willingness also to quote for any special apparatus to meet particular conditions. The catalogue is arranged in the form of single sheets held together by fasteners, so that, as other sheets are issued from time to time, these may be embodied in their correct places inside the cover.

ELECTRIC STOVES.—A small leaflet from Siemens Brothers Dynamo Works, Ltd. (Tysser Street, Dalston) contains particulars of the "Economic" electric stove. This apparatus was described in Electrical Engineering, May 13th, page 451.

PROTECTION OF OVERHEAD LINES.—A pamphlet entitled "Line Protection" is being issued by Messrs. Isenthal & Co. (85 Mortimer Street, Cavendish Square, W.). The way in which damage is apt to be done by excessive voltage due to static charges, atmospheric discharges, and low frequency surges is explained, and a system of dealing with these by connecting appropriate parts of the system to earth through condensers of the Moscicki type, combined with a series of spark gaps.

PORTABLE ELECTRIC DRILLS.—The latest list of manufactures of the Maschinenfabrik Oerlikon issued by Mr. C. Wüthrich (34-35 Oswaldestre House, Norfolk Street, Strand, W.C.), deals with portable electrically-driven hand-drilling machines for continuous and alternating current.

NEW CIRCUIT-BREAKERS

A NEW line in circuit-breakers has been introduced by Messrs. Spagnoletti, Ltd. (Goldhawk Road, Hammersmith),

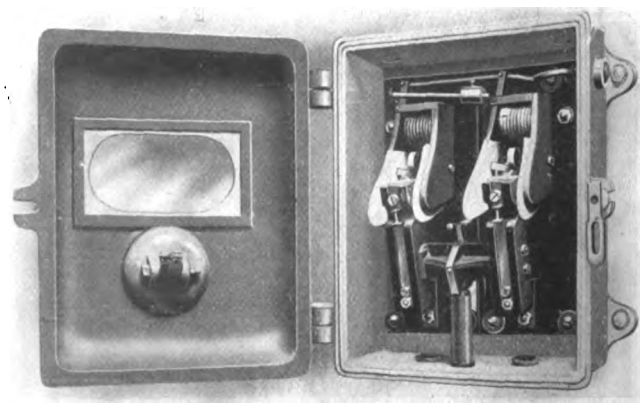

Fig. 1.—Two-pole Loose-handle Circuit-breaker.

under the name of the "Easy Replacement" circuit-breakers. These are constructed in single-, two- and three-pole designs

Digitized by Google

for switchboard and workshop use. The chief features of these switches are the low price and the small number of working parts. Front and side views of one pole of a three-pole switch are given in Fig. 2. The switch member comprises a porcelain or fibre body, *A*, pivoted at the bottom, and containing in a cavity an ordinary wire fuse, *D*, in series with the switch contacts. The laminated copper brush, *B*, attached to the body has an auxiliary flap with a renewable tip, *C*, which takes the

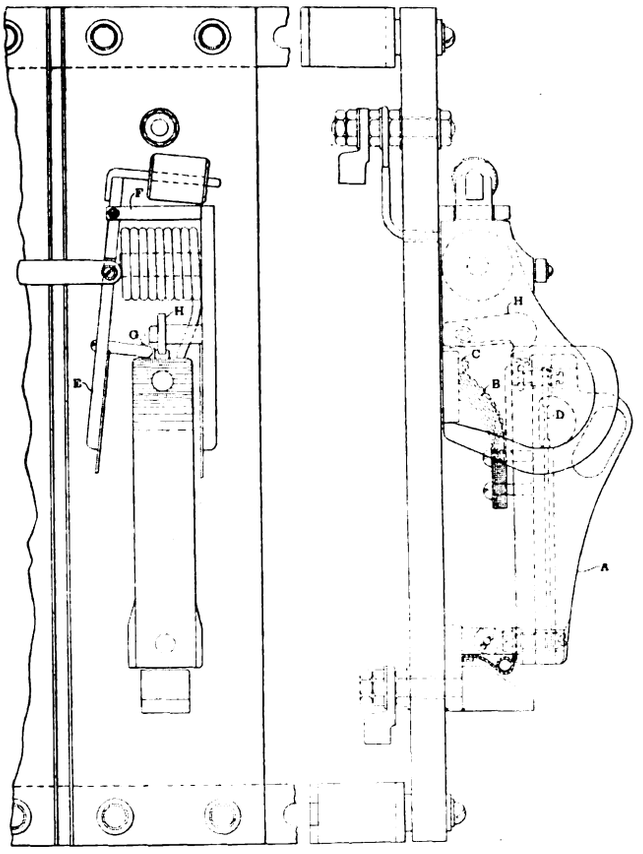

Fig. 2.—"Easy Replacement" Three-Pole Circuit-Breaker. Front and Side Views of One Pole.
(Scale ½ Full Size.)

arc at break. There are no springs in the switch at all. The body is held in the closed position against the action of gravity only by the detent, *H*, which engages with a catch on the body as shown. On an overload occurring, the armature of the series magnet is attracted, and the wheel, *G*, is pushed under the detent, which lifts and allows the switch to open. The overload magnet serves also as a blow-out magnet, and is wound so as to blow the arc out downwards away from the coil. The upper connecting piece, *F*, is of brass, so as to avoid short-circuiting the magnetic circuit, which is through the core of the coil and across the gap where the arc forms. Two iron flaps are provided to extend the area of the field, and each has a protecting shield of uralite. One flap, *E*, is pivoted, and serves as the armature of the overload magnet. The counter-weight on this flap can be adjusted so that the switch operates at the desired overload.

The fuse, *D*, is also situated in the magnetic field of the blow-out coil, and if for any reason the overload release fails to act, the fuse will blow if the overload is heavy. The switch illustrated in Fig. 2 is a 75-ampere one; it is set to release at 50 per cent. overload, or 112 amperes, and the fuse is such as will blow at 150 amperes. One of the most important features of the switch is that the whole current is effective in blowing-out the arc. On a short-circuit, for example, the whole of the short-circuit current passes through the coil, so that the instantaneous release of the switch and the destruction of the arc is ensured. We have no particulars of tests carried out on this pattern of switch for the higher pressures, but most satisfactory results have been obtained on 100- and 200-volt circuits. In the A.-C. switches, the core of the magnet is constructed of wire, but there is no other difference. As shown in Fig. 2, in two- and three-pole switches, the armature flaps are connected together by a bar, so that an extra current in one pole will operate all three. The illustration of Fig. 1 shows a two-pole switch with a loose handle in an iron case. It will be noticed that the two flaps are connected, that one weight serves for both, and that the switch can be released by hand by pressing the button on the side of the case. The fuses are clearly visible in this illustration, and it will also be noticed that the switch body is of fibre in this particular case.

A LIGHTNING ARRESTER RECORDER

THE protection of long high-tension feeders by suitably arranged spark gaps against the harmful effects of voltage surges is as important as the provision of lightning arresters for overhead lines. It is a very great convenience to be able to trace when and where these surges have occurred with a view to ascertaining their cause, and the arrangement used on the Heysham-Morecambe section of the Midland Railway for this purpose is of interest. This useful recording device was due to Mr. H. Brazil, of the Charing Cross, West-end, and City Electricity Supply Co., and the apparatus was shown by him at the Institution of Civil Engineers during the discussion on a Paper describing the electrical equipment of this railway (Electrical Engineering, November 18th, page 987).

A diagram of connections is shown in the accompanying figure. The spark gap in this particular case is of the "horn" variety, as supplied by the Lahmeyer Electrical Co. to the Charing Cross Co., with the "line" side of the gap faced with carbon. The other side is connected through a special non-inductive resistance and the primary of a small transformer to earth. The secondary of this transformer actuates a simple form of recorder which has been made by Messrs. Everett Edgecumbe and Co. for the purpose. This instrument has the movement of the pointer constrained by two stops, so that the passage of a current impulse due to the spark gap having been in action makes a V-shaped notch in the line traced by the pen. The circular disc chart revolves once in twenty-four hours, and the position of the stop is shifted by hand every day, so that the traces for every day of the week are concentric circles.

The resistance is of a form which is the outcome of a long

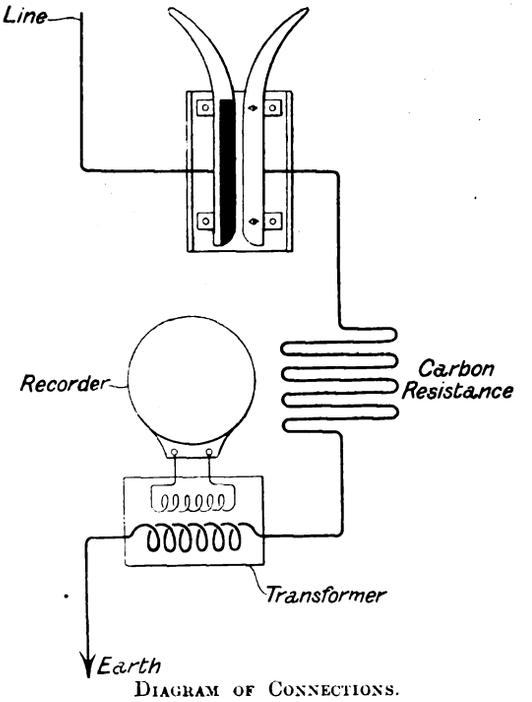

Diagram of Connections.

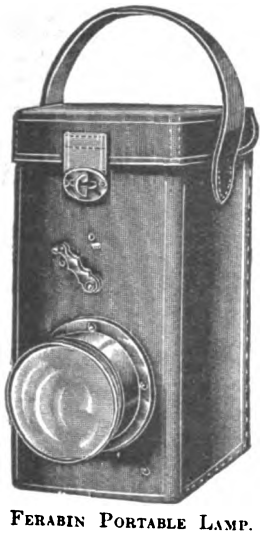

series of experiments, and consists of a zigzag groove of special shape in a fireclay block containing a special carbon powder supplied by the Morgan Crucible Co. It is capable of absorbing very considerable loads for some time without damage. This form of resistance has been in successful use all over the Charing Cross Co.'s H.-T. system for some time and has superseded the water resistances originally installed. A somewhat similar indicating gear is used there, but instead of a recorder being employed, a bell is caused to start ringing by a relay similar to an annunciator drop. The self induction of the transformer is not found to affect the working, but in cases where it might be objectionable, the transformer could easily be connected in shunt with a portion of the carbon powder resistance. The system has been adopted in several other E.H.T. stations.

General Engineering and Allied Trades Exhibition, Manchester, 1911.—We are informed that there is no foundation for the rumours that the exhibition has been abandoned. According to present arrangements it will be held in the spring of 1911, for six weeks, in a new building to be erected next year, which will be more than double the size of any now existing in any provincial city. The management is in the hands of the international Trade Exhibitions, Ltd., who so successfully organised the Manchester Electrical Exhibition of 1908.

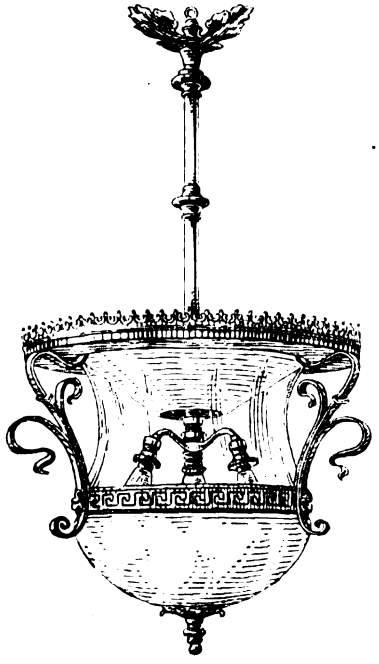
NEW PORTABLE LAMPS

SOME extremely neat patterns of portable lamps are being placed on the British market by the Ferabin Lamp & Electrical Accessories, Ltd. (118 Queen Victoria Street, London, E.C.). As shown in the accompanying illustration, which represents one of the smaller sizes, the lamp itself, a 3-volt Osram taking 0·4 amp., is placed in front of a suitable reflector in a lense cap fixed to the side of a light leather case. The battery in the case comprises two totally enclosed dry cells of sufficient capacity for 30 to 100 burning hours, according to the size of the case. One pattern, weighing only 6·4 lbs., gave, on an official test made by the Physical Laboratory of Hamburg, a continuous burning life of 57 hours, and after 24 hours' rest, a further 6½ hours' continuous burning were obtained. The lamp was taking 0·31 amp. at 3 volts. Smaller sizes with 35, 25, 15, 10, and 5 burning-hours' capacity can be obtained, and these are fitted in leather cases of various descriptions. The 7-hour "military" pattern has leather tags for attaching to buttons, and other patterns for from 15 to 35 continuous burning-hours for travellers have shoulder straps. In a special pattern for use on cycles or motors, the lamp is in a separate bulls-eye lantern, and is connected to the battery case by a protected flexible. Refills for all the above sizes are supplied, and these are stated to last 12 months in stock.



FERABIN PORTABLE LAMP.

Besides the above leather-cased patterns, there is a heavier lamp especially designed for use in mines, sewers, pipe subways, and similar places, where the presence of inflammable gases is suspected. This comprises a 57-hour battery in a gas-tight case of polished wood. It has two lamps; one on top of the case is switched on by giving the protected globe a half-turn, and the other (on the side of the case) has a switch. In both cases the contacts are inside the case, so as to make the lamp explosion-proof.

A SEMI-INDIRECT LIGHTING FITTING

THE accompanying illustration shows a novel form of lighting fitting introduced by the Ferabin Lamp & Electrical Accessories, Ltd. (118 Queen Victoria-street, London, E.C.). It comprises a basin or globe of opaline glass, an upper

THE "IMER" LAMP.

enamelled metal reflector, and a clear curved glass cylinder between the two to keep out the dust. The conical reflector ensures a wide and uniform distribution of light, and prevents any of the upwardly directed rays from being wasted, while the lower globe diffuses the direct light from the lamp cluster and protects the eyes from the glare due to the high intrinsic brilliancy of the individual filaments. The dust-proof construction is an important innovation, making the arrangement a distinct improvement on previous forms of semi-indirect lighting fittings. The interior cluster may consist of from one to five metal filament lamps, and when high candle-power lamps are used the fitting may well take the place of an arc lamp for shop or similar lighting. In an alternative design, there are exterior brackets for suspending lamps in fancy shades round the globe; this arrangement gives an artistic effect, but, of course, somewhat spoils the soft and uniform illumination obtained when all the lamps are behind the diffusing globe. This fitting is known as the "Imer" lamp, and can be supplied in various styles in brass or wrought iron.

CORRESPONDENCE

DANGER OF SHOCK FROM LIVE TROLLEY STANDARDS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I have noticed an article in your issue of November 25th dealing with the danger of shock from live Trolley Standards. When describing a certain form of Leakage Indicator you refer to various arrangements of this kind having been tried, but that they have proved more or less unsatisfactory and liable to failure. Possibly you are here referring to devices which embody principles, of which it can hardly be said that they prevent a shock, but solely give warning when the Standard has become dangerous.

The remarks, I think, can hardly refer to the special device introduced by me, and which is in use on some forty Tramways, including some of the largest in the Country. I might remind you that its special features are *actually the prevention of shock*, and not the giving of warning after which, possibly, fatal or dangerous results may readily ensue.

It relies on the principle of one of the Board of Trade's alternative regulations. This refers to the one which calls for the Electrical Connection of the Standard to the wheels in such a manner as to prevent the possibilities of the Standard becoming electrically charged. An audible and visual signal is combined with same.

Burton-on-Trent, December 5th, 1909.

Yours faithfully,
P. J. PRINGLE.
Borough Electrical Engineer and Tramway Manager.

ELECTRICAL DRIVING OF TEXTILE FACTORIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Referring to the letter on the above subject which appeared in your issue of the 2nd inst., the Council of the Bradford Engineering Society, after full inquiry, desires to confirm the report as a true and accurate record of the proceedings of the committee.

The complete report was typed and issued to every member of the committee several weeks before the meeting at which it was finally adopted, and no portion was therefore published without the knowledge of every member, and without full opportunity for discussion.

The committee decided from the outset not to enter into any discussion undertaken for the purpose of personal or trade advertisement, and it would obviously be useless to take notice of any further communication from gentlemen who so lightly repudiate the statements for which they themselves are responsible.

Bradford, December 7th, 1909.

GEORGE CARTER,
Secretary.

The Electrical Co.'s Single-phase Meter.—The Board of Trade have approved of the pattern and construction of the Electrical Co.'s single-phase alternating-current watt-hour meter, type LG., and of the means provided for fixing same.

London Traffic.—In the House of Commons, last week, the Hon. W. R. W. Peel asked the President of the Board of Trade whether the Government had taken any steps to give effect to the views put forward by the deputation from the London County Council to the Prime Minister on November 24th, 1908, with regard to the establishment of a traffic board for London. Mr. Churchill stated that since the deputation steps had been taken to strengthen the London Traffic Branch of the Board of Trade. The principal duties of this branch were to study the problem of London traffic, to report upon all schemes affecting London traffic, and to make an annual report on the whole subject for submission to Parliament. The branch performed many of the duties that would have been assigned to the traffic board recommended by the Royal Commission, and to this extent it might be regarded as a substitute for it, at all events for the present. Should an independent board be constituted by a future Act of Parliament it would find its task materially simplified and facilitated by the work now being carried out by the London Traffic Branch.

WIRELESS TELEGRAPHY BETWEEN SHIP AND SHORE.

A REVISED handbook of instructions for wireless telegraph operators working installations licensed by the Postmaster-General has just been issued. In the introduction the rules relating to ship installations are given, which may be of interest :—

The system used must be a "syntonised" or "tuned" system. Apparatus is deemed to be "syntonised" when the transmitting apparatus is so adjusted as to communicate with a receiver which has a corresponding adjustment, and to produce as little effect as possible on a receiver not having a corresponding adjustment. The speed of transmission and reception must, in normal circumstances, be not less than 12 words a minute, five letters being counted as one word. The power imparted to the apparatus must not, in normal circumstances, exceed one kilowatt. Larger power may be used if the ship finds it necessary to transmit messages at a distance of more than 300 kilometres from the nearest coast station, or if by reason of intervening obstacles communication can only be effected by an increase of power. The usual wave-length for ship stations is 300 metres, and *every ship station must be installed in such a way as to be capable of using this wave-length.* Other wave-lengths may, however, be used in addition to the 300-metre wave, on condition that they do not exceed 600 metres. A special exception is made as regards ships of small tonnage, which it might be impossible to equip with plant producing a 300-metre wave. Such ships may be authorised to use a shorter wave-length.

The greater part of the handbook consists of service instructions regarding the form and acceptance of radiotelegrams, regulations as to charges, and procedure to be observed by ship and coast stations. The international Morse code only is to be used, but certain abbreviations and special code signals are given, such as the distress signal, - - - — — — - - -. As soon as a station perceives the distress signal, it must suspend all correspondence, and must not resume work until it has made sure that the communication consequent on the call for assistance has been completed. When a ship in distress adds, after a series of distress signals, the call-signal of a particular station, the duty of answering the call rests with that station only. Failing any mention of a particular station in the signal of distress, any station which receives the call is bound to answer it. In doing this ships must beware of interfering with each other, and not more than one ship should answer if it is found that confusion results. A ship which knows from the strength of the signals of distress that she is near the ship requiring assistance should take precedence in answering and taking the necessary steps with regard to the distress signal.

On receipt of the signal — - - — - - — - - —, which indicates that a British man-of-war is calling a British coast station and has a message for transmission to the Admiralty, the coast station called must suspend all other communication (except such as may concern a vessel in distress) in order to deal with the message from the man-of-war. Any other stations (ship or coast) must also suspend communication (except such as may concern a vessel in distress) so far as this may be necessary to ensure satisfactory communication between the man-of-war and the station called. The ordinary international code used at sea for flag signalling may also be employed.

When a ship desires to call a shore station, the call must only be made, as a general rule, when the distance of the ship from the coast station is less than 75 per cent. of the normal range of the coast station or the ship, whichever is smaller, as given in the Official List. Before beginning to call, the ship station must adjust its receiving apparatus to the highest possible degree of sensitiveness, and make sure that the coast station which it wishes to call is not engaged in communication. If it finds that transmission is taking place, the ship station must wait for the first break before calling.

NEW DESIGN OF ELECTRIC LOCOMOTIVE

THE Westinghouse Electric & Manufacturing Co. of America has just completed a goods locomotive for the New York, New Haven & Hartford Railroad, which is described in a recent issue of the *Electric Railway Journal* (New York). It was designed primarily for handling fast goods trains, but will also be used for hauling heavy passenger trains. The locomotive will be given a thorough test with a view of handling all goods trains electrically in the future.

The 2-4-4-2 wheel arrangement has been adopted. Each truck has two pairs of driving wheels and a single pair of leading wheels, the driving wheels being held in alignment by cast-steel bar frames. The frames are placed outside the wheels, and are braced transversely under the centre of the locomotive by heavy steel castings provided with draw pockets in which the intermediate drawbar is seated. This bar transmits from one truck frame to the other the full tractive force developed by the motors of the leading truck. One truck has only a rotative motion about its centre pin, while the other has a backwards and forwards as well as a rotative motion, in order to compensate for the angular positions of the trucks and drawbar when the locomotive is traversing curves. The drawbars are pinned to cast-steel cross-ties, which brace the truck frames between the driving and leading wheels. The latter are mounted in radial-swing trucks of the Rushton type. The radius bars for these trucks are pivoted to the same cross-ties as the main drawbars. The wheel loads are equalised as in steam locomotive practice, the springs of the leading wheels being connected to the driving springs by equalising beams. One of the trucks is cross-equalised under the centre of the locomotive. The frame is spring-supported by the cross-equaliser on each side of the centre line. This arrangement will promote steady riding, and tends to prevent side rolling at high speed. The principal dimensions of this locomotive are as follows :—Gauge, 4 ft. 8½ in.; driving-wheel diam., 63 in.; truck-wheel diam., 42 in.; wheel base, rigid, 7 ft.; wheel base, total, 38 ft. 6 in.; total length, 48 ft.; over-all height, 13 ft. 9 in.; total weight, approx., 116 tons; weight on driving wheels, approx., 84 tons.

The electrical equipment comprises four 350-h.p. single-phase geared motors, together with the necessary apparatus for their operation on either the 11,000-volt alternating-current or 600-volt direct-current circuits. The motors are placed directly over the axles, and are mounted rigid on the truck frames. Each end of the armature shaft is provided with a pinion meshing with gears mounted on a quill surrounding the axle and carried in bearings on the motor frame, similar to the usual axle bearings. The quills are provided with six driving arms on each end, which project into spaces provided between the spokes in the driving wheels. Each of these arms is connected to an end of a helical spring, the other ends of the springs being connected to the driving wheels. This arrangement of drive smooths out the torque pulsations, and at the same time allows for vertical movement of the axles. In addition to the spring connection between the quills and drivers, flexibility is provided between the pinions and motor shaft, to equalise the torque on the gears. The centre of gravity of the motors, as well as that of the entire locomotive, is high, avoiding the transmission of strains and shocks from the track and roadbed to the motors.

The motors have twelve poles built into a solid frame, and are designed for forced ventilation. When operating on 25-cycle alternating current with forced ventilation, each of the four motors will carry continuously a load of 300 h.p. An air-blast transformer is provided. The control apparatus is of the well-known Westinghouse electro-pneumatic type. All four motors are connected in parallel, and are controlled by voltage taps on the main transformer. On direct current the motors are first grouped all in series, and then two in series and two in parallel, in combination with various resistance steps.

The locomotive can be operated from either end, and the system of control is such that two or more locomotives of this type can be coupled together and operated from one master controller. The control apparatus is arranged in the centre of the cab, with a passage on each side. Two pneumatically operated pantograph trolleys are provided for collecting current from the 11,000-volt overhead line. Pneumatically operated shoes are used to collect current on the direct-current third-rail section. The locomotive will be capable of hauling a 1,500-ton train at a speed of 35 miles per hour. When used in passenger service 600-ton trains will be hauled at a maximum speed of 45 miles per hour.

Slight Cable Trouble at Bermondsey.—The daily papers contain references to "cable explosions" which are stated to have occurred in Jamaica Road, Bermondsey, on Saturday afternoon last. On inquiry, we learn that a short-circuit developed on a distributor of the Bermondsey Borough Council supply system, in that road, but that only three consumers suffered an interruption of supply, and those for a very short time only. There were no explosions, but smoke was observed issuing from the ventilating apertures in a manhole cover. The fire brigade was called, and unfortunately a fireman who lifted a manhole cover and attempted to extinguish the flames before the arrival of the Council's men was slightly burnt about the face.

Royal Institution.—As has already been announced, the annual Christmas course of experimental lectures adapted to a juvenile auditory will be given by Mr. W. Duddell, F.R.S. The subject will be "Modern Electricity." The first lecture, on December 28th, will treat of first principles, and the second, on December 30th, is entitled "Electrical Instruments." Succeeding lectures, on January 1st, 4th, 6th, and 8th, will deal with Röntgen Rays, the generation of electricity, electric oscillations, and electric lighting respectively. The fee for non-members is one guinea, or for children under sixteen 10s. 6d. Other lecture arrangements before Easter include a course by Professor Silvanus Thompson, F.R.S., on "Illumination," and six lectures by Professor Sir J. J. Thomson, F.R.S., on "Electric Waves and the Electromagnetic Theory of Light." The Friday evening meetings will commence on January 21st.

LOCAL NOTES

ACTON.—*Electric Wiring.*—The Electricity Committee have instructed the Engineer to prepare a schedule of prices for the wiring of consumers' premises, the proposal being that local electricians who are willing to carry out the work on this scale, be allowed to do so. At present, one firm does all the Council's wiring.

AMSTERDAM: *Interruption in Electric Supply.*—It is reported in the daily papers that the electric light in the shopping centre of Amsterdam suddenly went out on Thursday owing to a short circuit. Great inconvenience was caused, and for many hours shops and restaurants had to use candles. Further confusion was caused by the telephones also going out of order for a time.

BELFAST: *Tramway Centre Poles.*—The Corporation have decided upon the removal of the tramway centre poles in High Street, to the footpaths, and to light the street experimentally by arc lamps placed on these poles.

Tramway Accounts.—The accounts of the Tramways Department for the eight months' working of the present financial year show a surplus of £14,530, after meeting all capital charges.

BOURNEMOUTH: *Sunday Tramways.*—The Corporation have again decided not to introduce a service of tramways on Sundays.

BRADFORD: *The Trolley Omnibus.*—The Tramways Manager, the City Engineer, and several members of the Tramways Committee are now on the Continent inspecting various tramways, including installations of railless electric traction.

BRIGHTON: *Supply to Small Consumers.*—With reference to our note last week under this heading, we are now able to give further particulars. A proposal has been made by a local firm for the wiring and fitting of premises. The suggestion is that the firm in question would provide all the wiring and fixtures, free of expense, risk, or responsibility, so far as the Corporation are concerned, the consumer being supplied through a prepayment meter at one penny per unit above the ordinary lighting rate, this extra penny being paid over to them in respect of the purchase of the installation, and when the consumption reaches 240 units per point installed, the fixtures become the property of the owner of the premises. The scheme would, of course, be open to all wiring contractors who cared to embark their capital in such a venture under similar conditions.

DENMARK: *Electric Traction.*—It is stated that a Swedish engineer has drawn up a scheme for the construction of an electric railway from Malmo to Copenhagen, passing under the Sound. The proposed line will have a length of about 147 miles, about ten of which will be in tunnel. The Swedish Government have appointed a special Commission to inquire into details.

DOVER: *Excess Expenditure.*—The Local Government Board have given their sanction to the following loans :—£300 to defray expenditure on transformers from April 1st, 1907; £630 to defray cost of booster; £600 to defray cost of chain grate stokers; £1,383 to defray expenditure on mains from April 1st, 1907, to September 30th, 1908; £1,441 to defray expenditure on services from April 1st, 1907, to September 30th, 1908; £500 to defray expenditure on services from September 30th, 1908; £1,675 to defray expenditure on mains from September 30th, 1908; £990 to defray excess expenditure of wiring consumers' premises.

DUBLIN: *Interruption to Supply.*—There was a temporary stoppage of the electric supply on Thursday, which was caused by one of the staff of a contracting firm, which is engaged in the Fleet Street Distributing Station. One of the contractor's men made a wrong connection, bringing into operation the Board of Trade safety switches, and thereby shutting down the supply to a large section of the city. The matter was quickly put right by the station staff, and the entire supply was restored within eight minutes. The man who was the cause of the accident was himself rather badly burned, but no one else was injured.

FALMOUTH: *The Trolley Omnibus.*—A proposal to install a system of the Railless Electric Traction Co. in Falmouth has been under consideration for some time, and we believe that Parliamentary powers will be sought next autumn.

HANDSWORTH: *Tramway Agreement.*—After negotiations extending over two years, terms have been arranged between the Council and the British Electric Traction Co. for the conversion of the lines in Handsworth to electric traction.

HULL: *Sunday Trams.*—The Sunday Traders' Association applied to the local magistrates last week for a summons against the driver and conductor of a Corporation tramcar for driving a car on Sunday. The magistrates refused the application, holding that tramcars were not included in the scope of the Lord's Day Observance Amendment Act.

INDIA: *Power Supply in Calcutta.*—In 1907 a licence was granted to Messrs. Hoare, Miller & Co., of Calcutta, for the supply of electrical energy in Calcutta and the surrounding districts. The scheme then proposed has since assumed much larger proportions, and the licence of 1907 is to be revoked in order to grant a similar one to the Bengal Coal Fields Power Co., Ltd.

ISLE OF WIGHT: *Railway Electrification.*—The Isle of Wight County Council Parliamentary and Railway Committee have convened a meeting of representatives of various Town Councils in the island to discuss a scheme for converting the railways to electric traction. An alternative proposal provides for the construction of light railways or electric tramways.

LIVERPOOL: *Tramway Energy.*—At the last meeting of the Corporation, Mr. Muspratt asked why the consumption of current for tramways had increased, although the mileage had decreased. The reply was to the effect that there were a larger number of top-covered cars in use than in the corresponding period of last year, and this mainly accounted for the increase in current consumption.

LONDON: *London County Council: Tramways.*—The Highways Committee recommend a scheme for the through running of tramcars over the system of the Leyton Urban District Council. The arrangement provides for the entire displacement of the cars of the District Council over the route in question, viz., from Lea Bridge Road to Whipps Cross.

Islington: Tramways.—The Works Committee recommend the Council to contribute one-third (£7,592) of the cost of widening Ball's Pond Road for the construction of tramways providing the Hackney Borough Council contribute a third of the expenses of widening the portion of the roadway in question, which is in their district. With regard to other tramways running from Southgate Road to Green Lanes, the committee recommend the Council in no circumstances to make any contribution towards the necessary street widenings.

MEXICO: *Electric Supply.*—It is announced that the Mexican Light & Power Co. is strongly opposing the application of the Puebla Tramways, Light & Power Co. for leave to extend their electric transmission lines in the Mexico City and the Federal district. In this connection it is announced that Mr. R. C. Brown, Managing Director of the Mexican Tramways Co., has resigned his seat on the Board of the Puebla Co.

MIDDLESBROUGH: *Electricity Works Assessment.*—The Borough Electrical Engineer has reported that his appeal against the assessment of the electricity works at £2,000 has failed.

Electric Wiring Powers.—The Corporation have given notice of their intention to promote a Bill in the next session of Parliament for, among other things, powers to wire consumers' premises, &c. The Electrical Contractors' Association have informed the Corporation that, unless the words "through a contractor but not otherwise" are inserted, they will have to oppose the Bill. The Association is to be asked for a more explicit definition of its requirements.

MIDDLESEX: *Tramways.*—A section of the County Council's tramways which has been constructed between Tally Ho Corner, North Finchley, and Cricklewood Broadway (*via* Regent's Park Road, Finchley Road, and Cricklewood Lane) will, it is expected, be opened for traffic within the next few days. This line will link the Great North Road and the Edgware Road systems, and it will then be possible to travel by electric car from Barnet to Acton.

PARIS: *Tube Railways.*—A petition has been presented to the Town Council in favour of the construction of tube electric railways.

PORT GLASGOW: *Electricity Supply.*—A sub-committee has been appointed by the Greenock Corporation to investigate the question of the supply of electricity in Port Glasgow. Leading shipbuilding firms and others in Port Glasgow are favourable to the project, and are hopeful that the negotiations will be successful.

ROTHERHAM: *Medical Inspection of Tramway Employees.* It has been decided that in future all tramway employees shall be periodically inspected by the Medical Officer of Health.

SOUTHGATE: *Electric Supply.*—An agreement has been entered into for the supply of electrical energy by the North Metropolitan Electric Power Supply Co. The company will take over the Council's Provisional Order, but the agreement reserves the right of the Council to re-purchase upon certain terms. Thus, if the re-purchase takes place in 14 years, the full capital is to be repaid to the company, plus 30 per cent.; if in 21 years, the full capital expenditure plus 22½ per cent; in 28 years, the full capital expenditure plus 15 per cent; and in 35 years, the full capital expenditure plus 7½ per cent.

SPALDING: *Provisional Order Revoked.*—The Board of Trade have revoked the Electric Lighting Order granted to the Council in 1905.

TROWBRIDGE: *Provisional Order Revoked.*—The Board of Trade have revoked the Provisional Order granted to the Western Electric Distributing Co., Ltd., in 1904, for Trowbridge and Bradford-on-Avon.

WARRINGTON: *Street Lighting.*—The Streets Improvement Committee have appointed a sub-committee to go into the question of street lighting. Some dissatisfaction has been expressed with the present electric lighting.

WINCHESTER: *Council and Electricity Co.*—As we recently announced, the Council appointed a consulting engineer to inspect the works of the Winchester Electric Light and Power Co., in view of the probable purchase by the Council under the Company's provisional order. The engineer has now made his inspection and a sub-committee has been appointed to deal with matters arising out of his report.

WATERTIGHT STARTERS

DEFY THE WET.

ADAMS MANUFACTURING CO., LTD.,
106, NEW BOND STREET,
LONDON, W.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of **9d.** per line (column width).

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of **1/-** for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to The Kilowatt Publishing Co., Ltd., 203–6, Temple Chambers, London, E.C.

BOROUGH OF EASTBOURNE.
Electricity Department.

THE CORPORATION OF EASTBOURNE are prepared to receive tenders for the supply and erection of:—

Section "L". One Steam-driven Surface Condensing Plant.

Specification, General Conditions and Form of Tender may be obtained on application to the undersigned, on and after the 10th December, 1909, on payment of one guinea, which will be returned on receipt of a *bona fide* tender. Duplicate copies can be obtained for the sum of 2/6, which sum will not be returned.

Tenders endorsed "Surface Condensing Plant" to be addressed to The Town Clerk, Town Hall, Eastbourne, and delivered on or before Monday, 17th January, 1910.

The Corporation do not bind themselves to accept the lowest or any tender.

J. K. BRYDGES, M.I.E.E.
Borough Electrical Engineer.

Electricity Works,
Eastbourne.
8th December, 1909.

METROPOLITAN BOROUGH OF STEPNEY
ELECTRICITY SUPPLY.
BLYTH'S WHARF GENERATING STATION
Coal and Ash Conveying Plant.

THE ELECTRICITY SUPPLY COMMITTEE OF the Metropolitan Borough of Stepney invite tenders from responsible contractors for the manufacture, supply and erection of a complete system of Coal and Ash Handling Plant, consisting of riverside electric crane and grab, automatic weighing hopper, gravity bucket or telpher type of conveyor, and auxiliary plant in connection therewith.

Copies of General Conditions, Specification, Form of Tender and Drawings may be obtained from Mr. Wm. C. P. Tapper, A.M.I.E.E., Borough Electrical Engineer and Manager, at No. 27, Osborn Street, Whitechapel, E., on payment of a deposit of five guineas. Deposits will be returned to *bona fide* tenderers after the tenders have been considered by the Council. Additional copies may be obtained on payment of one guinea each, which will not be returned. Copies of the specification, conditions and drawings may be inspected by application at the above-mentioned address.

Tenders, on the form supplied, endorsed "Tender for Coal and Ash Conveying Plant" must be delivered, signed, sealed, and addressed to the Chairman of the Electricity Supply Committee, at No. 27, Osborn Street, Whitechapel, E., not later than noon Thursday, Dec. 30th, 1909.

The Council do not bind themselves to accept the lowest or any tender, and in considering the tenders regard will be had to the completeness and working efficiency of any proposal, as well as to the amount of the tender.

The acceptance of any tender will be subject to the sanction of the London County Council to the necessary loans being obtained.

G. W. CLARKE,
Town Clerk.

Municipal Offices,
15, Great Alie Street, E.

BURGH OF GOVAN.
ELECTRICITY DEPARTMENT.

THE Electricity Committee of the Burgh of Govan are prepared to receive Tenders for:—

Contract No. 11 ... ... Turbo Alternator.
,, ,, 12 ... ... Rotary Converters.
,, ,, 13 ... ... High Tension Switchboard.

Specifications and forms of Tender to be obtained from T. C. Parsons, Burgh Electrical Engineer, Helen Street, Govan.

Sealed Tenders, endorsed according to the Contract, to be addressed to the Town Clerk, Town Hall, Govan, and handed in on or before noon December 13th, 1909.

(Signed)
J. A. HOUSTON,
Town Clerk.

CITY & COUNTY BOROUGH OF BELFAST.
TRAMWAYS & ELECTRICITY DEPARTMENT.

THE Tramways and Electricity Committee of the Belfast Corporation are prepared to receive Tenders for the following Plant:—

Specification No. J.1. One 1,500 Kilowatt Continuous Current Turbo Dynamo.
,, ,, J.2. Condensing Plant.

Specifications, with form of Contract, may be obtained from the undersigned, on payment of two guineas each, which will be refunded, provided a *bona fide* Tender has been sent in, and not withdrawn.

Extra copies may be obtained at 10/- each Specification, and 10/- per set of Drawings, which is not returnable.

Sealed Tenders endorsed "Tender for Turbo Dynamo" or "Tender for Condensing Plant," shall be lodged with the Town Clerk, City Hall, Belfast, not later than 11 a.m. on Monday the 10th day of January, 1910.

The Council do not bind themselves to accept the lowest or any Tender.

THOMAS W. BLOXAM, M.Inst.E.E.,
City Electrical Engineer.

East Bridge Street,
Belfast.

COUNTY BOROUGH OF DUDLEY.

APPLICATIONS are invited for the post of Assistant Engineer, applications to be in by December 14th, 1909.

Details of Appointment will be furnished upon application to

Borough Electrical Engineer,
Electricity Works,
Bull Street,
Dudley.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA.—It is stated in *Commercial Intelligence* that twenty municipalities in the neighbourhood of Melbourne are promoting a scheme for the erection of municipal electric supply works. A consulting engineer is to be employed to report upon the proposal.

Tenders are invited for the supply, delivery, and erection at the Lithgow Small Arms Factory, New South Wales, of an electricity generating station. Particulars from Mr. R. Muirhead Collins, representative of the Australian Commonwealth, 72 Victoria Street, London, to whom tenders by January 11th.

BEDFORD.—An induced draught plant is to be purchased at at estimated cost of £150.

BELFAST.—Tenders are invited for a 1,500-kw. continuous-current turbo-dynamo and condensing plant. (See an advertisement on another page.)

CHELTENHAM.—An application for a loan of £4,000 is to be made, made up as follows :—Mains, £2,000; services, £1,000; and meters, £1,000.

EASTBOURNE.—A steam-driven surface-condensing plant is required by the Corporation. (See an advertisement on another page.)

EDINBURGH.—We are now able to give further particulars of the scheme for providing extra plant at the Dewar Place generating station referred to in our last issue. Sir Alexander Kennedy, consulting engineer to the Corporation, recommends steel cooling towers in preference to brick, on account of the lower cost, the figures being £12,000 and £18,000 respectively. The probable alternative to increasing the output at McDonald Road by the installation of condensing plant, would be the erection of a power station at some distance, and to generate high-tension current. This, however, is regarded as likely to be more extensive and less efficient than the present system.

GOVAN.—The Electricity Committee invite tenders by December 13th for a turbo-alternator, rotary converters, and high-tension switchboard. (See an advertisement on another page.)

LLANIDLOES (Montgomery).—The Council have an electric lighting scheme under consideration.

LONDON: *Bermondsey.*—Owing to the excessive loads on the Spa Road feeder it has become necessary to strengthen same at a cost of £319.

Islington.—Mains are to be extended at a cost of £750.

Stepney.—Tenders are invited by December 30th for a complete system of coal- and ash-handling plant. (Full particulars are given in an advertisement on another page.)

SOUTH AFRICA.—The Natal Town Council have deposited a bill for borrowing £60,000 for tramways and £100,000 for electric lighting and power.

WALSALL.—At the Local Government Board inquiry last week concerning a loan of £35,000 for electrical extensions, opposition was offered by the South Staffordshire Tramways Joint Committee, on the ground that they have offered the Corporation a supply in bulk which, it was claimed, would prove to be more economical than the arrangements proposed in connection with the scheme now placed before the Local Government Board. Mr. A. S. Barnard, the Borough Electrical Engineer, admitted that he had no figures to show that it would not pay the Council to accept this offer. It was a fact, however, that the form in which the energy would be supplied by the company was not that in which it could be transmitted to their own consumers, and this would necessarily increase the price to the Corporation.

YORK.—It is proposed to apply for a loan of £2,475 for electrical extensions, made up as follows: Services, £1,100; motors, £800; meters, £575.

Miscellaneous

LONDON: *Southwark.*—The Board of Guardians require a 38 instrument central battery telephone installation for their East Dulwich Grove Infirmary. Particulars from Mr. A. P. Richardson Shill, 70A Basinghall Street, London, and tenders to the Clerk of the Guardians, John Street West, Blackfriars, London, by December 16th.

SWITZERLAND.—The Government propose to spend the sum of £48,000 during the next financial year on the telephone system, and £1,464 for electric measuring and testing instruments.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—The L.C.C. invite tenders for the wiring and fitting for electric lighting and bells of the Poplar Divisional Offices, Stafford Road, E. Particulars from the Chief Engineer to the Council and tenders by December 15th.

School, Gainsborough Road, West Ham, E. F. E. Hilleary, Secretary, West Ham Education Committee.

Factory for Pinchin, Johnson & Co., Ltd., paint and varnish manufacturers, Minerva House, Bevis Marks, E.C.

Fire station, Brunswick Road, Bromley-by-Bow (£12,660). Architect, W. E. Riley, L.C.C. Education Committee, Spring Gardens, S.W.

W.C.—Water Board Central Offices, W.C. (£100,000). W. B. Brian, Chief Engineer, Metropolitan Water Board, Savoy Court, W.C.

PROVINCES.

BEXHILL-ON-SEA.—School. Clerk to the Education Committee, Town Hall, Bexhill.

BIRMINGHAM.—Schools, Dixon Road. T. H. Buckland, architect, Education Offices, Birmingham.

COVENTRY.—School, Broad Street (£9,000). Builders, Orr Bros., Foleshill.

KING'S NORTON.—Education offices. Architect, Mr. Moor, Education Offices, King's Norton.

MERTHYR TYDVIL.—School, St. David's. Mr. Thackeray, school architect, Town Hall, Merthyr.

MIDDLESBROUGH.—Alterations and additions to North Ormesby Hospital (£2,500). Architects, J. M. Bottomley, Son & Wellburn, 28 and 30 Albert Road, Middlesbrough.

NORTHAMPTON.—Additions to premises, Kettering Road and Exeter Road, for the Co-operative Society, Ltd., Northampton.

Additions to Council school, St. James' Road, for the Education Committee.

OXFORD.—Education offices. County Architect, New Road, Oxford.

WALLSEND.—Hospital. Architects, J. T. Davidson, Station Road, Wallsend.

WORTHING.—Skating rink. Architect, A. Crouch, Worthing.

Faraday House Old Students' Association.—On Friday last the old students' smoking concert was held at Faraday House, Dr. Alexander Russell, the Principal, being in the chair. The scientific library of the late Principal (Mr. Hugh Erat Harrison), comprising some 2,000 volumes, which has been presented to the institution by his family, was formally presented by Mr. R. Wallis-Jones on behalf of the family, and accepted on behalf of the Governors by Mr. Robert Hammond. During the intervals of the concert Mr. Arthur Wright gave a demonstration of his apparatus for solving algebraical equations, and other demonstrations included the Reason Co.'s 1-ampere-hour meter and the Thorpe electricity meter.

Trinidad Bitumen.—The majority of the distributing engineers who use bitumen are very imperfectly acquainted with the various sources of supply and the treatment which the crude bitumen has to undergo before being ready for the market for the "solid" system of cable-laying. In an interesting pamphlet which the British Electrical Trade Supply & Bitumen Co. have issued, analyses and other information with regard to lake and land bitumen are given. Mr. A. E. H. Dussek, the author of the pamphlet, sounds a note of warning against using refined coal-tar pitch or "British asphalt" (*i.e.*, pitch mixed with mineral powder) in place of the Trinidad product. Mr. Dussek asks us to state that he will be pleased to send a copy of the pamphlet to any of our readers who may be interested in the subject.

WHY BUY FOREIGN DOORS? We compete. Doors from 4/- each. Engineers supplied with any description of cable casing, manufactured woodwork, timber of all kinds. Creosoted timber and underground troughs. C. JENNINGS & Co., Timber Merchants, General Woodworkers, 955, Pennywell Road, Bristol.

ELECTRICAL ENGINEERING BOOKS AT HALF PRICES!! Books on Electrical, Engineering, Technical, *and all* other subjects supplied. Sent on approval. State wants. Catalogue No. 98, Post Free. Books bought. W. & G. FOYLE, 135, Charing Cross Road, London, W.C.

TENDERS RECEIVED AND ACCEPTED

DUBLIN.—The tender of the General Electric Co., Ltd., for 750 meters at £977 14s., has been accepted.

EASTBOURNE.—The tender of the Aron Electricity Meter, Ltd., has been accepted for the supply of 100 meters.

EPSOM.—The Council have placed an order with the Foster Arc Lamp & Engineering Co., Ltd., for flame arc lamps of the company's new "Q" type.

LEYTON.—A contract is to be entered into with Messrs. Johnson & Phillips, Ltd., for arc lamps for street lighting purposes.

LONDON: *London County Council.*—The following tenders have been received for covering with asbestos tape various high and low tension cables used in connection with the Council's tramways :—Johnson and Phillips, Ltd. (accepted), £1,241; Western Electric Co., £1,520; Siemens Bros. and Co., Ltd., £1,818; Callender's Cable and Construction Co., Ltd., £1,978; Vauxhall Engineering Co., £2,097; British Insulated and Helsby Cables, Ltd., £2,465; R. W. Blackwell and Co., Ltd., £2,510; W. T. Henley's Telegraph Works Co., Ltd., £2,737.

The Stores Committee have accepted the following tenders :—Electric carbons, W. Geipel and Co. Electrical fittings : Elliott Bros., Ltd.; Falk, Stadelmann and Co., Ltd.; W. McGeoch and Co.; and A. Round. Insulating materials : British Insulated and Helsby Cables, Ltd.; British Westinghouse, Ltd.; Edison and Swan United Electric Light Co., Ltd.; General Electric Company, Ltd.; J. N. Hardy and Son; India Rubber, Gutta Percha and Telegraph Works Co., Ltd.; J. G. Ingram and Son; D. Jarowslaw; Micanite and Insulators Co., Ltd.; Ruberoid Co., Ltd. Electric cables and wires : Hooper's Telegraph and India Rubber Works, Ltd.; Yorkshire Cable Co., Ltd.

Southwark.—The Council has accepted the tender of the British Insulated & Helsby Cables, Ltd., at £44 for 110 yards of 0·75 single cable; also the tender of the Aron Electricity Meter Co., Ltd., for two 400-ampere meters at £27, and two 25-ampere meters at £15 15s.

Woolwich.—Contracts have been placed with Messrs. Siemens Bros. & Co., Ltd., for the supply of cable at £2,984, and with the Albion Clay Co., Ltd., for ducts, at £765.

SHEFFIELD.—The Council has accepted the tender of the British Electric Transformer Co., Ltd., for eight sets of transformers and switch gear (each set consisting of one 200 k.w. main transformer, one 20 kw. auxiliary transformer, and one set of two wire series control gear, £222 each; also two 200 k.w. transformers, £121 each.

WALLASEY.—Messrs. Imeson Finch & Co. have received a contract for the supply of 326 poles, 7½ miles of trolley wire, and the necessary crossings, bonds, ears, &c.

APPOINTMENTS AND PERSONAL NOTES

The proposal of the Derby Electric Lighting Committee to increase the salary of Mr. E. C. Bossier, Mains Superintendent, from £150 to £170 per annum, with further increases of £15 per annum to £200 per annum, was strongly opposed at the last meeting of the Corporation. It was pointed out that £200 per annum was a fair average remuneration for a mains superintendent, and an amendment to vary the terms of the proposed increase was lost.

Mr. Howard Foulds, Secretary of the Electrical Standardising, Testing and Training Institution, Faraday House, Southampton Row, London, has been elected a member of the Holborn Borough Council.

The Dudley Corporation require an Assistant Electrical Engineer. (See an advertisement on another page.)

The York Corporation recommend the appointment of Mr. Chipper as Traffic Inspector at a salary of £2 10s. per week.

Wireless Telegraph Notes.—The *Times* Wellington correspondent states that the New Zealand House of Representatives have empowered the Executive to make regulations requiring passenger vessels to carry wireless telegraph apparatus. It is probable that some of the vessels trading between New Zealand and Australia will be equipped within a few months. A conference of representatives of Australia, New Zealand, and the Pacific Islands is to meet at Melbourne on December 16th.

According to *Elektrotechnik und Maschinenfabrik*, a conference of the German marine insurance companies is to be held shortly for the purpose of urging the adoption of the Telefunken system of wireless telegraphy by the German merchant service. It is stated that this action is being taken with the hope of arresting the efforts of the Marconi Co., to obtain the monopoly in wireless communication, and is justified by the most successful results which have been obtained recently between the station at Nauen and a Woermann steamer on the route to Kamerun.

The German Admiralty has, says the *Globe* Kiel correspondent, decided to extend wireless telegraphy on land and sea to the extinction of pigeon post service. The sum of £75,000 is to be spent in this connection.

It is announced that the United Wireless Telegraph Co. of America have decided to put down extensive works in the neighbourhood of Liverpool.

COMPANIES' MEETINGS AND REPORTS

ELECTROMOBILE CO.—The accounts for the year to August 31st show that the debit to profit and loss account is increased to £6,511, after providing for debenture interest, depreciation on carriages, and special expenses *re* issue of mortgage and debenture stock.

BULLERS.—The report for the year to July 31st, 1909, shows a profit of £4,839, including £906 brought forward. To this is added £5,000 from reserve fund, and after meeting preference dividends, and a dividend of 1¼ per cent. on the ordinary shares, a balance of £464 is carried forward.

PROVINCIAL TRAMWAYS CO.—The accounts for the year to September 30th show a balance of £16,169, after meeting debenture interest, preference dividends and interim dividends on the ordinary shares. The sum of £8,000 is transferred to reserve and depreciation, and £500 to meet expenses of issue of debenture stock. A final dividend of 4s. per share is recommended on the ordinary shares, making 7s. per share for the year.

NORTH METROPOLITAN ELECTRIC POWER SUPPLY CO.—At an extraordinary general meeting on Friday, the issue of further debentures to the value of £25,000 was authorised.

SIEMENS-SCHUCKERTWERKE-GES., BERLIN.—A dividend of 10 per cent. is recommended for the year ending July, 1909. The business of the first three months of the present year is said to have been very satisfactory.

INDIA RUBBER, GUTTA PERCHA, & TELEGRAPH WORKS CO.—The report for the year ended September 30th, 1909, shows a net profit of £57,927, in addition to £51,980 brought forward. The directors recommend the payment of the half-yearly dividend on the 5 per cent. preference shares, and a dividend of 15s. per share, free of income tax, making a total of 10 per cent. for the year.

ISLE OF THANET ELECTRIC TRAMWAYS & LIGHTING CO.—The accounts for the year to September 30th show a net profit of £7,851. It is proposed to place £3,000 to reserve; to pay a dividend of 1¼ per cent. on the preference shares; to transfer £1,500 towards permanent-way maintenance; and to carry forward £1,476. The sale of electrical energy during the year increased by nearly 10 per cent. The meeting is on December 16th.

BLACKPOOL AND LYTHAM TRAMWAYS CO.—The accounts for the year to October 31st enable the directors to pay 3 per cent. on account of the arrears of interest on the mortgage stock.

A New Flame Arc Lamp.—Reference is made in another column to an order secured by the Foster Arc Lamp & Engineering Co. for a number of flame arc lamps of a new type for the Epsom Urban District Council. The lamp in question is a new departure from existing types of flame lamps, and is claimed to be very steady and silent in burning, with a carbon consumption per hour costing not more than 0·18d. A novel form of electrode is employed, consisting of a number of carbons moulded together side by side. By this arrangement extinguishing of the lamp when changing from one carbon to another is avoided. There are also one or two other novel points about its design.

The Faraday Society.—At the annual general meeting of the Faraday Society, held on November 30th, the following officers and council were elected to serve for the session 1909–10 :—President : Mr. J. Swinburne, F.R.S. Vice-Presidents : Mr. G. T. Beilby, F.R.S., Sir R. A. Hadfield, F.R.S., Prof. A. K. Huntington, Dr. Ludwig Mond, F.R.S., Lord Rayleigh, F.R.S., Prof. A. Schuster, F.R.S., and Mr. Ernest Solvay. Treasurer : Dr. F. Mollwo Perkin. Council : Messrs. E. J. Bevan, Bertram Blount, A. C. Claudet, W. R. Cooper, S. Z. de Ferranti, F. W. Harbord, W. Murray Morrison, H. K. Picard, J. L. F. Vogel, and N. T. M. Wilsmore.

Telegraph Traffic and Movements of Cable Ships.—We are unable to announce any repair to the French Co.'s West India system, the breaks due to the hurricane still awaiting mending. This is, however, no doubt due to the c.s. *Pouyer-Quetier* being engaged in restoring the cables between Paramaribo and Cayenne, and Cayenne and Salinas, both of which were again on the active list on the 28th ult.—By now the steamer probably is at work on the Puerto Plata-Martinique section.—On the 2nd inst. the cable between Nagara and Kartal was interrupted for a while, and on the same day the line between Bagdad and Bassorah ceased operating. The restrictions recently notified on messages to Turkey in Asia have been cancelled, and telegrams may now be accepted as usual.—The Bagdad-Bassorah line was restored on the 3rd inst., but was down again on the 6th, while the cable between Nagara and Kartal was also down on the 6th as well.—The Assab-Perim cable has not yet been repaired, although it has been waiting attention since July 8th last. The Dakar-Conakry cable has not yet been put through, and the Réunion-Mauritius cable is still down. The cable of the Direct West India Cable Co. was working as usual on November 29th, and in view of it being necessary to charter a repairing vessel, a quick repair has been effected. The cable steamer *Relay* undertook the work.

Digitized by Google

NEW COMPANIES

CROSS & CROSS, Pleck Road, Walsall.—Capital, £2,000. To carry on the business of electrical and constructional engineers.

DE MARTIS ELECTRIC STORAGE SYNDICATE, 61 Gracechurch Street, London.—Capital, £25,000. To carry on the manufacture of electrical accumulators, and to adopt an agreement with H. De Martis.

ACADIA SYNDICATE, 4 Bishopsgate Street, London, E.C. —Capital, £12,000. To supply electricity for all purposes, and to acquire the Moneton Electric Street Railway, Heat, & Power Company.

ELECTRICITY GENERATING CO., 16 Great George Street, Westminster, London.—Capital, £1,000. To carry on the business of electric supply and dealers in dynamos, accessories, &c.

BURFORD ELECTRIC LIGHT & POWER CO., registered by Jordan & Sons, Ltd., 116–117 Chancery Lane, London. —Capital, £400. To supply electricity, &c.

PERTH TRACTION & DEVELOPMENT CO., 30–31 St. Swithin's Lane, London, E.C.—Capital, £10,000. To acquire a concession for constructing tramways in Perth (W.A.), &c.

SILICO BITUMEN CO., 13 Walbrook, London, E.C.— Capital, £4,000 in £1 shares (2,000 six per cent. accumulated preference). To carry on the business of bitumen manufacturers for electrical insulating purposes, &c., and to supply electric fittings and accessories.

SILICAWARE.—Registered by Messrs. Cruesemann & Rouse, 85 Gracechurch Street, London. Capital £63,000. To acquire an interest in any patents relating to electric furnaces and processes for electrical refining, and to adopt an agreement with Dr. Wolf Burckhardt.

DERWENT VALLEY ELECTRIC POWER CO.—Capital, £2,000. Registered by Messrs. Minet, Pering & Co., 7 St. Helen's Place, London, E.C. To carry on the business of an electric power company.

QUEBEC RAILWAY, LIGHT, HEAT & POWER.—An application has been made for the incorporation of this company and the amalgamation of the following companies :—Quebec Railway, Light, Heat & Power Co., Quebec Gas Co., Frontenac Gas Co. and several electric power companies, including the Jacques Cartier Co., the Seven Falls, and the Canadian Electric Power Companies.

F. BURKS & CO.—37 Port Street, Manchester. Capital £10.000. To manufacture electrical instruments, telephones, &c.

NEW MOTIVE POWER CO.—Registered by H. W. Clarkson, 85 Gresham Street, London, E.C. Capital £20.000. To construct, manage, or control in England railways, tramways, and trolley ways, and to carry on the business of electricians, &c.

MADEIRA ELECTRIC LIGHTING CO.—75 Lombard Street, London, E.. Capital £30,000, in £5 shares. To acquire from the Receiver for the debenture holders of the Madeira Electric Lighting Co. the concession to supply electricity in Funchal, Madeira. Subscribers : H. Hirst, 71 Queen Victoria Street, London; H. Kahn, 75 Lombard Street, London; G. T. Moody, Lorne House, Dulwich; and A. I. S. Basen, 71 Queen Victoria Street, London.

FERABIN LAMP & ELECTRICAL ACCESSORIES.—266 Mansion House Chambers, London, E.C. Capital £15,000. To adopt an agreement with A. Wedekind for the acquisition of a certain invention, and to supply electrical accessories, &c. Subscribers : J. S. Romer, 20 Bucklersbury; L. Ridout, 26 Dorset Square, London, N.W.; J. W. W. Agnew, "Lyndale," Turnpike Lane. Hornsey; J. G. Riadore, 100 Piccadilly; A. E. Rice, 20 Bucklersbury, London; W. H. Herod, 17 Frinton Road, Stamford Hill, London, N.; H. J. Wright, 69 Black Boy Lane, Wood Green.

PENINSULA ENGINEERING CO.—Suffolk House, Laurence Pountney Hill, London, E.C. Capital, £5.000 in £10 shares. To take over the business of electrical and general engineers, &c., carried on in Spain and Portugal by Messrs. Hastings, Roberts & Co.

THOMAS FOREIGN PATENTS.—Registered by Jordan & Sons, Ltd., 116-117 Chancery Lane, London, E.C. Capital, £500. To acquire certain patents for an electro-mechanical power transmission system.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £60 15s. to £61 5s. per ton (last week, £60 10s. to £61 10s.).

BANKRUPTCIES, LIQUIDATIONS, WINDINGS-UP, &c.— A meeting of Headland's Patent Electric Storage Battery Co., Ltd., will be held at the offices of the liquidator, Mr. G. D. Price, Finsbury House, Blomfield Street, London, on January 4th, 1910, at 4 p.m., to receive an account of the winding-up.

AGENCY.—Messrs. Feld Bros. & Co., of 25 Budge Row, London, have appointed Mr. S. W. Bunting, consulting and electrical engineer, 49 Park Avenue, Whitley Bay, as their sole representative for Newcastle, Middlesbrough, and district.

CANADIAN AGENCIES WANTED.—A London firm manufacturing motors and dynamos is open to appoint Canadian agents.

A London firm wishes to appoint Canadian firms as agents for the introduction of their improved electric arc lamps.

Further particulars relating to the above may be obtained from the High Commissioner for Canada, 17 Victoria Street, London.

A SIMPLEX COMPETITION.—With the object of making the contents of their new catalogue better known, Messrs. Simplex Conduits, Ltd., are inaugurating a competition in the Christmas number of *Installation News*. The task set is to give a name to fittings, of which a portion only will be illustrated. Copies of the new list will be sent to any of our readers on receipt of a trade card.

THE ELECTRICAL CO.'S INSTALLATION BUSINESS.— We are informed that the A.E.G. have disposed of their installation and consumers' business to a new Company called the A.E.G. Electric Co., Ltd., and that from January 1st the Electrical Co., Ltd., will again be strictly wholesale, and deal only with electrical contractors, electrical supply companies, and electrical wholesale houses.

MISCELLANEOUS CITY NOTES

SAO PAULO TRAM, LIGHT, & POWER CO.—A quarterly dividend of 2½ per cent. is announced.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO.—An interim dividend of 2s. 6d. per share has been declared for the September quarter.

GLOBE TELEGRAPH CO.—An interim dividend of 2s. per share has been declared for the September quarter.

A LARGE SWISS WATER-POWER STATION

A RECENT issue of *La Revue Electrique* contains a short description of a large water-power station at l'Akersand, not far from Visp (Viège), in the canton of Valais, Switzerland, which was inaugurated in October. The station in question is the property of the Société des Usines Electriques de la Lonza, and supplies electrical power to an electrochemical works at Visp, which was opened at the same time.

Power is derived from the waters of the Saaser Visp river, from a point on the stream at Balen, at an altitude of 4,780 ft. A canal in a tunnel over seven miles long brings the water to the head of the pressure pipes, which are of steel, and three in number, one about 2 ft. 4 in. in diameter, and the others each about 1 ft. 8 in. in diameter. The available fall is about 2,400 ft., and the amount of water is given as 880 gallons per second, corresponding to about 30,000 h.p. It is not clear, however, whether this is the minimum or the maximum amount available. The hydraulic work has been carried out under the direction of M. Boucher, consulting engineer at Lausanne.

The power-house is designed to contain five sets each of 5,500 to 7,000 h.p., of which one is already at work, and the second in course of erection. The alternators are being supplied by the Siemens-Schuckert Co., and generate direct at 15,500 volts three-phase, so that step-up transformers are not required. They run at 500 r.p.m. The transmission line to the chemical works at Visp is nearly four miles long, and consists of twelve copper wires, each 14 mm. diameter. It is designed for the whole ultimate output of 30,000 h.p.

Digitized by Google

TESTS OF METAL FILAMENT LAMPS

A PAPER by Mr. F. H. R. Lavender, read on December 1st before the Birmingham Local Section of the Institution of Electrical Engineers, contained the results of some interesting tests of metal filament lamps of various makes.

Six different makes were tested, and six 100-volt, 25-c.p. lamps of each were run at six different constant voltages, ranging from 95 to 107·5 volts. The Paper describes the connections used and arrangements for supply, partly from batteries and partly from the mains. The lamps were run continuously day and night, and two sets, that is, 12 lamps, were tested each day by a Bunsen grease-spot photometer against a Fleming carbon lamp standard by means of an Osram sub-standard. The method of working out was as follows :—The candle-powers of all six lamps of a set were first plotted on one sheet against the life in hours as abscissæ. The life curves were transferred to separate sheets, and curves giving the number of candle-hours obtained from the lamp for a particular life. From the price of the lamp, "pence per candle-hour per lamp" curves were constructed. (The price of the tantalum lamps was taken at 2s. 6d. each, and of all the others at 3s. 6d.) On the same sheets the consumption curves corresponding to the lamps were plotted. From these the watt-hour curves were obtained. The watt-hour curve, together with the candle-hour curve gave the curve of $\frac{\text{watt-hours}}{\text{candle-hours}}$. This gave the average efficiency, and, therefore, with a certain price of current, the cost per candle-hour for any pre-determined length of life. From this curve, together with that of lamp cost, the "total pence per candle-hour" curves were plotted for current at 2d., 4d., 6d., and 8d. per unit. When the lamp had been burning a sufficiently long time the ordinates to these curves reached a minimum

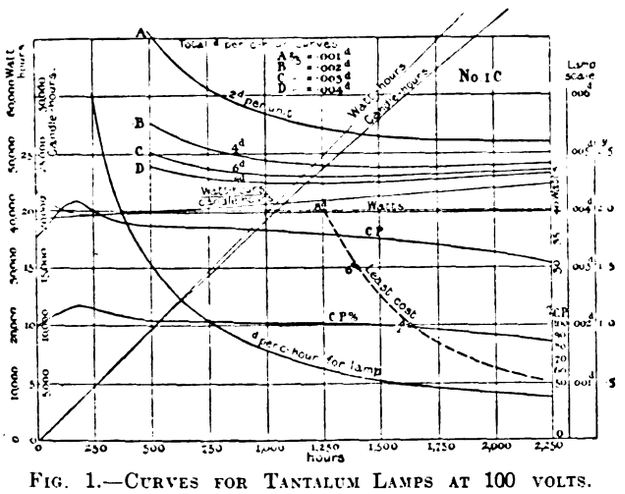

FIG. 1.—CURVES FOR TANTALUM LAMPS AT 100 VOLTS.

value. This at once gave the most economical life for the lamp.

As an example, one of the many sheets of curves reproduced in the Paper is given in Fig. 1. This relates to a set of tantalum lamps run at their rated voltage of 100 volts. Further curves obtained from the total cost curves, gave the relation between the cost of energy in pence per unit and the useful life. In Fig. 2 are curves giving the relation between the least total cost of light (for lamp and energy) and the voltage for four typical cases. These were constructed by taking the minimum points of the total cost curves. The dotted curves are drawn through the minimum points.

Taking first the results with the tantalum lamps, all the candle-power curves show a distinct rise at first and then a gradual fall, the slope of which depends on and increases with the voltage at which the lamp is run. Taking current at 5d. per unit as an average price, and the lamp run at rated voltage, then it pays to throw the lamp away as soon as the candle-power has fallen to 3 per cent. below its original value. This result appears startling at first, considering the large initial cost of the lamp. However, by the time this point is reached the lamp has been burning for 1,500 hours at the best possible efficiency for the given potential difference at its terminals, so that the cost of the lamp per candle-hour has become small. In most cases the "total cost" curves are flat near their minimum value, so that the exact time to scrap the lamp is not very clearly marked. When the lamps are run at a low voltage the efficiency curve rises slowly, and the smashing-point is not reached until the "lamp cost" curve has become fairly flat, which means a long economical life, for the candle-power is low but varies slowly. On the other hand, when run at a higher voltage the changes in the lamp take place more rapidly, the

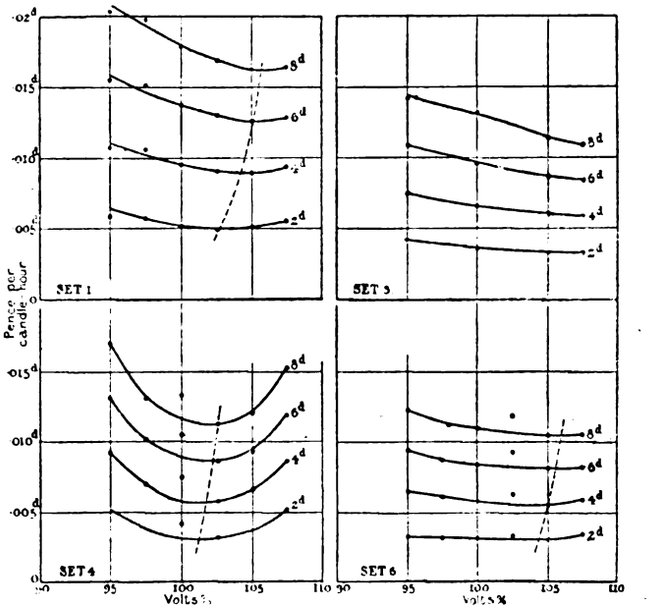

FIG. 2.—TOTAL COST OF LIGHT AT DIFFERENT PRICES OF CURRENT FOR VARIOUS MAKES OF LAMP.
SET 1. TANTALUM. SETS 3, 4, AND 6. TUNGSTEN.

efficiency curve rises quicker, and consequently the economical life is shorter.

The curves in Fig 3, plotted from the result with the tantalum lamps, bear out the conclusion that the economical life decreases with an increase in voltage, and show the dependence of the useful life on the voltage with various prices for current. The steepness of the least-cost curves (connecting price of current with the economical life) increases with the voltage. It is partly due to the greater rapidity of the changes in the lamps at higher voltages and partly due to the improvement in

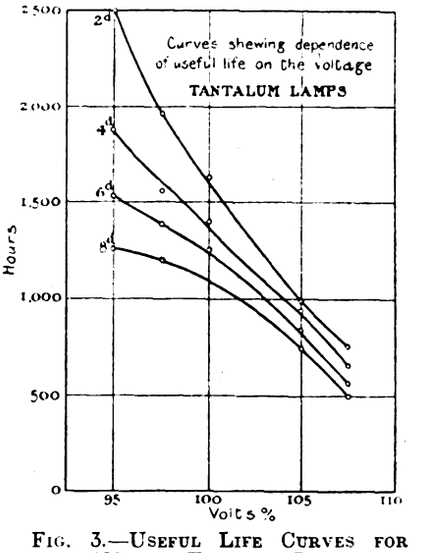

FIG. 3.—USEFUL LIFE CURVES FOR 100-VOLT TANTALUM LAMPS.

the efficiency. Owing to this smaller consumption the effect of a variation in the price of current on the total cost becomes less, and the curve partakes more of the shape of the lamp-cost curve, which is still steep at these voltages when the economical life is reached. The result of this is that when lamps are being much overrun, the price of current becomes a small matter when considering the length of life. From the curves in Fig. 2, it is seen that the dearer the current the higher the potential difference at lamp terminals, and therefore the efficiency at which it pays to burn it.

Digitized by Google

The curves become more concave as the price of the current goes up owing to the greater effect of the efficiency on the total cost. It appears that it would be good practice to overrun the lamps from 2 to 6 per cent., and for a life of 1,300 to 700 hours, according to the price of current. With current at 4d. per unit the drop in candle-power from the initial giving the most economical life appears to be about 5 per cent.

Many of the remarks made on tantalum lamps apply equally well to tungsten lamps, but the initial rise in candle-power in tantalum lamps is in most cases not apparent. The candle-power drop is very rapid at first, and then less so until almost horizontal. The total cost-curves in Fig. 2 all show the same characteristics as those for tantalum lamps. In one or two instances the points do not lie on the curve but fall above it. This is due to the fact that the lamp corresponding to the point was a poorer one than the others. These curves in the case of Set 3 show a continual drop without a minimum point. This is due to a very great improvement in the efficiency of the lamps at higher voltages without a corresponding shortness of absolute life or greater steepness of the life curves. The increased potential difference has an effect on the absolute besides the useful life. The useful life of tungsten lamps is much longer than that of tantalums. If carelessly handled the absolute life would probably be shorter owing to the greater fragility of the filament. It may be noted that the area of bulb exposed to blackening is greater in the case of all the tungsten lamps tested than in the case of the tantalums. This would help to prolong the efficient life.

The allowable drop with tungsten lamps is on the average greater than with tantalum lamps, owing to the prevailing absence of an initial rise and the presence of an initial drop of candle-power as mentioned above. A factor which effects the mechanical life of a lamp is the method of anchoring the filament at the pip end. Some trouble was experienced with the lamps in which the tops of the loops are fastened by a globule of glass to a short piece of wire cemented to the end of a small coiled spring. When such a lamp was burning a small jar was sufficient to detach the loop from the spring, owing to the glass softening. As far as tightness of filament is concerned the best lamps were those in which the loops were simply threaded through a loop at the end of a piece of nickel wire, the other end of which was stuck into the top of the glass pillar. The tantalum lamps were much tougher than the tungsten ones.

The following table gives a comparison of the different makes. Below it are given for comparison some figures for carbon lamps taken from Mr. Hirst's Paper, read before the Institution, reduced to British candle-power at 9d. per lamp. The cost of energy has been taken at 4d. per unit.

Lamp.	Initial Candle-power.	Volts per cent.	Useful life.	Mean efficiency.	Candle hours.	Cost per 1,000 Hours.		
						Renewals.	Current.	Total.
			Hours.			d.	d.	d
Set 1 Tantalum	21·50	105·0	970	1·87	22,200	1·350	7·50	8·850
2 Tungsten	24·20	105·0	1,500	1·45	32,400	1·300	5·80	7·100
3 ,,	30·00	107·5	2,300	1·29	67,464	0·640	5·16	5·800
4 ,,	28·50	102·5	2,000	1·32	53,138	0·790	5·28	6·070
5 ,,	31·20	107·5	1,900	1·34	47,500	0·880	5·36	6·240
6 ,,	26·50	105·0	2,350	1·22	55,770	0·750	4·88	5·630
Carbon 100 volt	15·10	100·0	1,000	4·94	14,560	0·619	19·75	20·369
,, 200 ,,	14·95	100·0	1,000	4·06	14,400	0·628	16·25	16·878

The figures giving the life are those giving the best economy. The actual life in some cases was much greater. Many of the lamps were burning well after 3,000 hours.

From these tests it appears that the cost of lighting with tungsten lamps amounts to about 6·2d. per 1,000 candle-hours. If tantalum lamps are used the cost is about 8·8d., or 42 per cent. more. For carbon lamps, the cost is about three times as much as for tungsten. In the case of metal filament lamps 85 per cent. of the cost is paid for the energy consumed, and 15 per cent. for the lamp itself, while with carbon lamps this latter item only amounts to 5 per cent. of the whole, so that it may be almost neglected.

The author also carried out some tests of the temperature at the outside surface of the bulbs, and found this for a tantalum lamp to be 68° C. when new, and 95° C. after 1,400 hours, and to vary from 40° C. to 53° C. for new tungsten lamps, and from 48° C. to 69° C. after 1,400 hours. The temperature of the bulbs apparently increases with the life. This may be due to the presence of the black deposit on the bulbs, which absorbs some of the rays, and consequently becomes heated. The ends of the bulbs keeps comparatively cool, because the radiation is much less in that direction. The lamps were found to flicker more than carbon lamps when placed on an unsteady circuit. This is owing to the lower thermal capacity of the filaments. For this reason they are not suitable for circuits with alternating currents of low frequency. For slow changes in potential difference about the normal, however, the alteration in candle-power, as is well known, is not so great as is the case with carbon lamps. Curves were given to illustrate this, and some results of tests of spherical distribution of candle-power were also included.

DISCUSSION.

After an abstract of the Paper had been read, Mr. H. W. HANDCOCK gave a short *résumé* of the Paper by Mr. Dykes and himself, on "The Present Aspect of Electric Lighting," read at the meeting in London on November 25th (see ELECTRICAL ENGINEERING, December 2nd, p. 1025).

Dr. W. E. SUMPNER (Municipal School of Technology, Birmingham) opened the discussion on the two Papers. He pointed out that what ordinary engineers wanted to know was the maximum useful life of the lamp; in other words, the point at which it can with advantage be smashed. It was quite beside the point to lay down that the lamp should be removed when its candle-power had dropped to 3 per cent. of its initial value, since this point could not be determined by the ordinary consumer. A method proposed by Dr. D. K. Morris was useful. If the cost of the lamp and the cost of the current were plotted as abscissa and the candle-hours as ordinates, it would be noticed that after about 300 hours' burning the curve of total cost became a straight line. In the case of metal filament lamps there was no definite smashing point, as the percentage drop in candle-power was so small. Messrs. Handcock and Dykes's Paper was useful as dealing with the question of getting small consumers on to the mains. It was a step in the right direction to make the tariff simple.

Mr. M. SOLOMON (General Electric Co.) was of opinion that Mr. Lavender's Paper did not give the information required, viz., when the lamp should be thrown away. As a rule, the natural end of a lamp was due either to its breaking or to the light given being insufficient. There was great liability of error in preparing curves such as were given in the paper. The first set of candle-power curves were deduced from the actual observations by a smoothing-out process, which depended largely on the personal equation. The conclusion, therefore, that lamps should be discarded when the candle-power had dropped 3 per cent. was not on a sound basis, since it was certain that considerable errors might have been made subconsciously. The figures given by the makers were, in his opinion, very close. For the sake of easy comparison variations should be given as percentages.

Mr. A. LINDSAY FORSTER (Messrs. Chance Bros.) pointed out that Mr. Lavender's Paper dealt with the comparative merits of different types of metallic filament lamps instead of contrasting these with carbon filament lamps. There was a great deal of useful information in the Paper, but the conclusions arrived at were not made clear in the Paper, and a careful *résumé* of the Paper bringing out the important points would be valuable. With regard to Messrs. Handcock and Dykes's Paper, he was in the peculiar position of being in control of both gas and electric plant, but up to the present had not considered it feasible to introduce electric lighting. However, the advent of the metal filament lamp altered the situation considerably, and he would be obliged to reconsider the question in view of the new conditions. The Contract system proposed by Messrs. Handcock and Dykes was on the same lines as that obtaining in the case of water supply, and worked quite satisfactorily in this instance.

Mr. R. ORSETTICH (General Electric Co.) looked at Messrs. Handcock and Dykes's proposal from the point of view of a consumer. He asked to what class this tariff was to be applied. The ordinary consumer, with penny-in-the-slot meter, cannot afford to pay 12s. per lamp. If it applied to consumers with 10 or 15 lights, the load factor of 80 per cent. was altogether too high, and would more probably be 35 per cent. A flat rate of 4d. or 4½d. should be charged. In Aston the charge was 3½d., which was too low. The income per lamp per annum at Aston was 3s., and a charge of 10s.—12s. would be unjust, and would kill electric lighting. Consumers often started with a small number of lights as an experiment, but the fixed charge suggested would prevent extensions or alterations in the size of lamps. The number of consumers could be largely increased with the present rates, and their load factor would be quite low.

Mr. NEEDHAM (British Thomson-Houston Co.), stated with respect to the candle-power curve in Mr. Lavender's Paper, that the initial rise in candle-power was due to the cementing together of the filament, which was originally in the form of powder. Some makers ran their lamps for some time in order to age them before delivery to purchasers. Lamps were rated by manufacturers at a somewhat lower voltage than the normal in order to ensure a long life. Tungsten lamps could be run as long as they hold together, as the percentage drop in candle-power is so small.

The CHAIRMAN stated that the point of view of the customer and of the manufacturer had been dealt with, but suggested

Digitized by Google

that the view of the station engineer would be valuable. In his opinion the metal filament lamp had increased the output of the station.

Mr. MILNES (Birmingham Corporation) said that the growth in revenue of the Birmingham Electric Supply Department was practically the same as in the days of the carbon lamp, but the growth in candle-power was much greater. The life of the lamp depended very largely on the variation in voltage, and it was very important that a lamp of a voltage higher than the supply voltage should be used. The Contract system of charging could be applied for small consumers. An experiment had recently been tried with small houses having five lights each. There was one service and one meter for six hours. The charge was 6d. per week in the summer, and 1s. per week in the winter, and this was strictly paid in advance. Prepayment meters had also been used, the charge being 5d. per unit.

Mr. W. FENNELL (Wednesbury Corporation) showed output curves for his station from 1904 to 1909. The increase in 1904–5 was fairly large, in 1906 it dropped a little, in 1907–8 it recovered to its previous rate, and in 1909 there was a regular boom. The best canvasser was a reduced bill. Many of the long-hour consumers in his area had not been touched. As regards the Contract system, he had been in charge of a station in the west of Ireland, where this was in force, but now that the price of meters was so low there was no great advantage to be gained by it, and it was open to the objection that a certain amount of house-to-house inspection was necessary to ascertain what the consumers were doing.

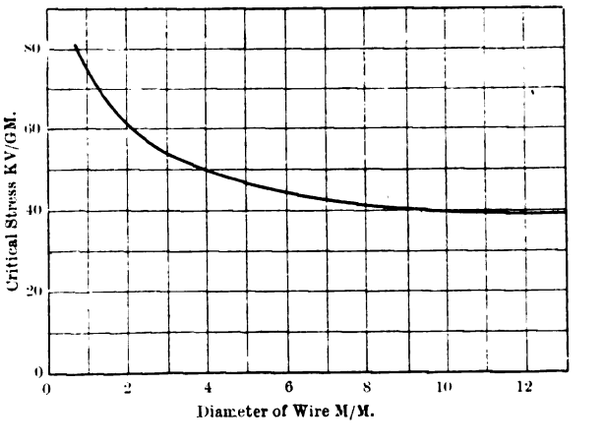
Mr. HANDCOCK briefly replied to the discussion as regards his Paper, and defended the Contract system vigorously. Water supply had been conducted for years on these lines, and no great trouble was experienced. If special holders were supplied for different sizes of lamps, there was no more risk of the consumer substituting lamps of higher candle-power than of tapping the supply mains, on the station side of the meter. The long-hour consumer had long borne too large a share of the burden of the standing charges, and it was only right that the short-hour consumer should pay his due proportion of these.

HIGH-TENSION TRANSMISSION

A PAPER entitled "Recent Developments in the Transmission of Electrical Energy at High Tensions on Overhead Lines," by Prof. E. W. Marchant and Mr. E. A. Watson, was read before the Manchester Local Section of the Institution of Electrical Engineers on Tuesday, November 30th. The authors pointed out in their introduction that the transmission of electrical energy over long distances was a problem which had received greater attention in America than in Europe, and mentioned as examples great developments which have taken place at the Niagara Falls and on the Pacific slope of Western America.

In order that economical transmission of electric power may be made over long distances it is necessary that a high voltage should be employed. The standard pressure at present in use is 60,000 volts three-phase. In several cases stations have been designed for pressures up to 110,000 volts; in many of these, lower pressures are being used until the load on the station is sufficiently large to necessitate the higher pressure being employed. Higher voltages are undoubtedly possible at the higher altitudes of Colorado and the Nevadas than could be used on similar installations in our great manufacturing districts; but, allowing for all effects of climate and atmosphere, there is no doubt that there is no great technical difficulty involved in the use of much higher voltages than have hitherto been attempted in this country. In the early plants the voltage was limited by the insulation of the transformers. Improvements soon raised this, until the limit was the line insulator, then of the ordinary pin type; but with the advent of the suspension-type insulator, this limit has been removed, so that, at the present time, the possible voltage is only limited by the production of a corona or brush discharge from the line itself. The authors give the following formulæ for the electric stress produced in the neighbourhood of the wire :—

Two parallel wires :— $$\frac{V}{2a \lg_e \frac{d}{a} \sqrt{1+\left(\frac{d}{2h}\right)}}.$$



One wire and earth :— $$\frac{V}{a \lg_e \frac{2h}{a}}.$$

Three wires at corners of a triangle (ordinary three-phase arrangement) :— $$\frac{V}{\sqrt{3} \lg_e \frac{d}{a} \sqrt{1+\left(\frac{d}{2h}\right)^2}}$$

(where V = line voltage; d = distance apart of wires; h = height above ground; a = radius of wire).

They point out, however, that the value of the electric stress which can be allowed depends on a good many factors, some of which have not been very definitely investigated, and suggest the figures shown in the curve reproduced, combined with a factor of safety which should have, approximately, the following values :—Large towns or industrial districts, 1·8 to 2; ordinary open English country, 1·5; mountainous or other districts far from any source of contamination of the air, 1·2.

With the exception of the few plants in France and Switzerland, all modern transmission schemes employ three-phase alternating current. Though there are certain cases in which direct current would possibly be the more suitable, the authors consider that the conditions found in America appear to be better satisfied by the three-phase alternating-current system. The question of frequency is settled more by the question of standardisation than by any other consideration. The standard frequencies on the American Continent are 25 and 60 cycles, the latter being used almost universally for lighting purposes. It is, however, distinctly high for long-distance transmission. In some cases the transmission is at 25 cycles, and frequency changers are employed. Practice, however, seems to vary in different parts of the country, the Niagara plants, for example, all generate at 25, while 60 is standard on the Pacific Coast and in most other parts. The large 60-cycle plants on the Pacific Coast have very large charging currents. The operation of a number of widely distributed central stations on a common distributing network has presented few difficulties in actual practice. As a matter of fact, synchronising through a long transmission line is an easier matter than synchronising in a

RELATION OF CRITICAL STRESS AND DIAMETER OF WIRE.

central station. This impedance of the line acts in the same way as the coreless choking coils, which have recently been fitted in some stations to assist synchronising, and cuts down the cross-currents which would otherwise flow when a bad phase is made, to very much smaller dimensions.

The protection of the overhead line against atmospheric discharges is a matter of great importance. The lightning arresters formerly in use were those of the well-known Würts pattern or the carbon rod spark arresters. In nearly every station that was visited by the authors, however, both at Niagara and on the Pacific Coast, these arresters are being displaced by those of the electrolytic type. These arresters are kept charged by being connected every other day direct to the overhead line, but normally they are arranged with a spark-gap between them and the line. The most effective protection against lightning is undoubtedly the earthed wire, which not only acts as a screen against the electrostatic effect by charged clouds moving in the upper regions of the atmosphere, but it also provides a path to earth more direct than that of the line wire over the whole length of the transmission line, and thus prevents a lightning stroke from striking the transmission line. In most cases where the earthed wire is fitted, however, the best practice is to connect a lightning arrester of the ordinary type to the line as an additional safeguard.

Asynchronous generators consisting of ordinary induction

Digitized by Google

motors run above synchronous speed are now sometimes employed in large networks fed from a number of stations. They are extremely robust in construction, and can be thrown straight on to the line without synchronising and short-circuited with immunity.

An efficient system of telephones is a matter of importance in the operation of a large network. With 60,000-volt schemes the usual practice is to arrange the telephone line about 10 ft. below the transmission line, and to support it on insulators on the same poles. In order to avoid mutual induction effects, the telephone lines are transposed at frequent intervals. Transposition of the telephone line is, however, not sufficient to prevent induction, as the inductive effect from the three main lines are sufficiently different in magnitude on the two telephone lines to give large currents along the whole length of line. Electromagnetic induction may be almost completely avoided by transposing both the transmission line and the telephone line. In order to obviate electrostatic effects as far as possible at the telephone, the wires are connected by a split-choking coil at the ends of the line, and the centre-point of this coil is connected to earth.

The arrangement of the transformer on the high-tension network is one in which considerable discrepancy of practice exists. Briefly stated, the advantages of the delta methods of connection are that if one of the phases breaks down the other two will supply power to the extent of two-thirds of the capacity of the transformer, and if an earth occurs on one leg of the transmission line it does not affect the running of the system provided the insulators on the other two wires are sufficiently large to stand the concatenated pressure of the system. On the other hand, with the star arrangement, the size of insulator used need only be large enough to withstand the star pressure of the system, and the neutral-point can be earthed and the pressure between each line and earth definitely equalised.

Regarding the most economical voltage at which a transmission line should be worked, Kelvin's Law states that the most economical section of conductor for a given transmission is that for which the capital charge on that portion of the capital expenditure which is proportional to the area of the conductor shall be equal to the annual cost of wasted energy. This, continue the authors, is based on the condition that the total charge for transmitting energy along the line shall be a minimum, but a sounder condition to apply to a transmission line is that the ratio of the total cost of transmitting energy to the revenue earned shall be a minimum, and if this condition is applied we find that the cost of wasted energy must be equal to the whole charge for interest and depreciation on the transmission line. The second factor which determines the size of the conductor is the working pressure. With high pressures the possibilities of the formation of a corona and the loss of considerable energy by brush discharge is one that requires careful consideration, and the section of the conductor must not be reduced below that for which such effects are produced. Another factor which might be expected to have some influence on the choice of voltage used for transmission is the cost of insulating the line. The common practice is to work the line to give a known percentage drop, and to increase the voltage on the line as the load on it increases, until at the full load the pressure on the line is the maximum for which it was designed at a predetermined drop. The usual efficiency of transmission on most of the schemes seems to be about 90 per cent., the copper drop being of the order of 10 per cent., and the total drop due to resistance and inductance about 15 per cent.

The Paper then passes on to set forth some of the prevailing features of modern American practice in water power stations. After some remarks on the hydraulic part of the equipment, which necessarily varies a great deal with local conditions, they say that the general arrangement of the plant of a modern water-power station is fairly well standardised, although not to anything like the extent of an English steam-driven station. General practice appears to favour generation at about 11,000 volts with oil-insulated water-cooled transformers raising the pressure to that of the line. Taps are frequently provided for working at less than the full voltage, if desired, and this is often done during the early stages of the plant, before it gets its full load. In some cases the transformer is considered as forming one unit with its generating plant. In one case seen by the authors, the transformers were treated as forming part of the line, a bank of three single-phase transformers being connected thereto without any high-tension switchgear at all.

Considerable diversity exists in the design of the switchgear, both cell type and open pattern arrangement being found, the numbers of each being about equally divided if the Niagara plants are included. If these are left out, the majority of the stations visited had their high-tension gear and busbars quite exposed, although neighbouring parts were generally separated by brick partitions. Copper or aluminium rods supported on large pin-type insulators were used in all the plants except that of the Central Colorado Company, where the rods were hung from above by means of suspension insulators such as were employed on the line. The line is usually brought into the station through large porcelain bushings, sometimes in the station wall, but in the higher voltage plants placed in the roof. Just outside the station are placed the lightning arresters. Inside the station the line goes to a choking coil, usually a plain copper spiral hung in the air, but sometimes an elaborate arrangement with oil insulation. In all cases but one the line was fed through oil and disconnecting switches from the high-tension "bus." Instrument transformers are frequently employed on the high-tension side of the station, although they tend to assume rather formidable proportions. Small electrostatic potential indicators are used on the high-tension conductors to indicate to the operators whether these are alive or not. They consist simply of a pivoted aluminium vane moving in front of a fixed section and acting on a similar principle to an ordinary electroscope. The insulation of the high-tension leads where they pass through the case of the transformer is a most difficult problem. A terminal for 100,000 volts is quite a large thing, even if condenser-type insulation be adopted. The object of the so-called condenser-type insulation is to obtain a terminal over the surface of the insulation of which the potential gradient shall be as nearly as possible uniform. This is done by embedding in the insulating material metal laminæ whose dimensions are so chosen that the capacity between any two laminæ is the same, this giving a number of equal increments of potential from the case of the transformer to the live conductor.

Practically all plants in the States working at less than 65,000 volts appear to use pin insulators, while above this the suspension type is employed. Glass insulators are not used on the highest voltage lines. With suspension insulators the ordinary triangular arrangement of conductors is not, of course, practicable; generally if only one line is installed the three conductors are placed in one horizontal plane. When two lines are run, three conductors can be placed on each side of the tower and suspended from three cross-arms. The towers are generally galvanised steel shipped in sections which are bolted together at the site. Creosoted wooden poles seem unknown in either Canada or the States, and the life of an untreated pole is generally short.

In all the early installations the insulators were mounted on wooden pins, usually of eucalyptus-wood coated in oil or boiled in paraffin. The two difficulties which have arisen in connection with these are the digesting of the pin-screw due presumably to the formation of nitrogen compounds by brush discharges from the wire, and burning of pins due to leakage current. The wooden pins are now being steadily displaced by iron pins, either with lead screws for screwing into the insulators or by iron pins cemented into the insulators.

The two metals chiefly used for an overhead line are aluminium and copper; although a great many lines have been erected with aluminium as the conducting material, the tendency in the newer stations is to use copper. The advantages of copper are that it has great mechanical strength, and is a material which is easily jointed and soldered; it is not so electropositive as aluminium, and is therefore not so likely to corrode in a foggy atmosphere. On the other hand, aluminium has the advantage of being a lighter metal than copper for the same conductivity, and is a less expensive material to erect. The conductor used is, in nearly every case, a stranded one. This is necessary for heavy current transmissions, on account of the great stiffness of a solid conductor. Even when stranded with seven or nineteen wires the cable is often too stiff for convenient handling, and a hemp-cord is inserted. Another reason for the use of the hemp-cord is that when a seven-strand cable is erected in the ordinary way, it is usually the centre strand which breaks when the cable is strained. Aluminium has a higher coefficient of expansion than copper, and will sag more with increase in temperature than copper. A disadvantage of the larger cross-section of the aluminium line is that the effect of wind pressure on it is more marked than on a copper line, but, on the other hand, the risk of a corona effect and brush discharge with an aluminium line is considerably lessened.

The Paper concluded with a few remarks on sub-station equipment.

DISCUSSION.

Mr. T. L. MILLER opened the discussion with a few remarks on the details of hydraulic practice given in the Paper, and emphasised the importance of the generators being so constructed that in the event of the governor failing and the speed running up they would keep well within limits. In speaking of transmission lines, he said that the latest development was

Digitized by Google

concrete poles, which were lighter than iron poles, and not subject to the same depreciation as either the wood or iron.

Mr. J. S. PECK (British Westinghouse Co.) noted, regarding electrolytic arresters, that the authors stated that it was customary to connect the arresters to the line every other day. This was done to make sure that the film on the aluminium plates was kept up to its full strength, for if the film were allowed to deteriorate, the arresters might take an enormous current in the event of a lightning discharge. He did not think, however, that this was universal practice, and he was informed that certain types of electrolytic arresters showed no deterioration in the film after a year's service. He did not see why properly transposing the telephone line should not eliminate the effects due to electromagnetic induction. Electrostatic effects, however, could not be eliminated in this manner.

Mr. S. L. PEARCE (Chief Electrical Engineer, Manchester Corporation) referred to the high capital costs of water-power stations, and considered on account of this that they had not after all such a very great advantage in comparison with modern steam turbine plants. Dr. Marchant had touched on the possibility of using overhead transmission in this country. In the case of Manchester, two or three years ago, in connection with the supply to such outlying districts as Denton, Droylsden, and Audenshaw, the advisability of an overhead line had been considered, and it was calculated that, at the best, something like 20 per cent. could be saved, as compared with an underground system. Certain restrictions, however, were laid down, certain roads would not be allowed to be crossed overhead, and by the time these difficulties had been met, there was practically little saving to be effected. Even in America he believed that some engineers, for the sake of absolute reliability, preferred, rather than to risk failure, to refrain from tacking an overhead line to a system which has already 75 to 80 per cent. underground to commence with. Regarding alternating-current distribution, if the consumer wanted lighting as well, an arrangement of inter-connected star-balancing coils could be used to give the neutral point.

Prof. A. SCHWARTZ referred to experiments made between spheres in which the dielectric strength of air was found to be as low as 28 kilo-volts per centimetre. During some experiments at the School of Technology, steam had been discharged through a pipe on to a wire carrying a pressure of 100,000 volts, and they found that the steam was deflected very strongly away from the wire. In view of this, he suggested that possibly the immediate neighbourhood of the wire was really the driest point in the district. He also gave some figures showing how much greater the strength of porcelain was in compression than in tension, and said the insulator ought to be designed always so that the porcelain was in compression at the point of support.

Mr. MILES WALKER (British Westinghouse Co.) went into the question of long-distance transmission in this country from the coalfields to large towns, and said that, assuming voltages of 50,000 to 100,000 volts to be practicable, it appeared to be more efficient to transmit electricity than to transmit coal if the scale were sufficiently large. He worked out the cost of a suitable line for transmitting 100,000 kw. to London from a coalfield 100 miles away at £440,000, or say, £44,000 per annum. Now it was possible to generate electricity at the pit's mouth at a cost for coal of only 0·1d. per unit if the demand was very great and the load factor was as high as 33 per cent. Under the same conditions in London it was not likely that the cost for coal would ever be less than 0·2d. That is to say, that the efficiency of transmission of coal was not greater than 50 per cent. Now 100,000 kw. with a load factor of 33 per cent. means $2·8 \times 10^8$ units per annum, and with a saving of 0·1d. per unit there was a total saving of £120,000 per annum.

Mr. C. H. K. CHAMEN said that it was now an established fact that overhead lines at 10,000 or 20,000 volts worked as satisfactorily as cable systems. From his own experience, 10,000-volt lines could be worked in this country without any protection against lightning or any line protection whatever, except spark-gap and carbon-rod protection devices at the power station.

Dr. E. ROSENBERG (British Westinghouse Co.) spoke on the subject of asynchronous generators. The advantages of this type of generator were often over-estimated. It had been assumed that the induction generator could be thrown straight on to the line without synchronising, but this could only be true for very small machines.

Mr. A. P. M. FLEMING referred to the suggested employment of inter-connected star-balancers to obtain a neutral point for lighting voltages, and pointed out that their use would obviate the necessity for bringing out neutral connections on the main transformers. He also considered the advantages of suspension over pin insulators, and was of opinion that the former could be employed economically for lower pressure than the limit given in the Paper.

Mr. A. B. MALLINSON said that the weakest parts of an overhead transmission line as at present installed in this country were the guard nets required where crossing public roads, &c., which, he thought, caused more trouble than they prevented.

Mr. G. HARLOW called attention to schemes where it has been proposed to do away altogether with high-tension switchgear, and to carry out all switching on the L.T. side of the transformers.

Mr. S. J. WATSON (Borough Electrical Engineer, Bury) put forward a few of the advantages of the Thury system. He did not see a great future for long-distance transmission from collieries, in view of the great capital cost of the transmission lines. He felt sure that it would be cheaper to bring the fuel and have the power station near the centre of the population.

The authors replied briefly.

ANNUAL DINNER OF THE GLASGOW LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS

SOME 240 members and friends assembled on Wednesday, the 1st inst., for the eighth annual dinner of the Glasgow Local Section of the I.E.E., at the Grosvenor Restaurant, Glasgow. Mr. G. E. Tidd presided.

Sir Donald MacAllister (Principal of Glasgow University), in a happily worded speech, proposed the toast of "The Imperial Forces," to which Admiral Sir Charles Campbell and Colonel Hugh D. D. Chalmers replied, the latter making some reference to the usefulness of the proposed technical branch of the Territorial Army. Sir John H. A. MacDonald, the Lord Justice Clerk, submitted the toast of "The Corporation of the City of Glasgow," and gave some interesting personal recollections of the growth of its railways, tramways, and other engineering businesses connected with the city. Baillie Archibald Campbell responded, and said that he hoped that electricity would be of great aid to them in solving the problem of the purification of the air now exercising their minds. The speech of the evening was probably that of Prof. Archibald Barr (Glasgow University), who submitted the toast of "The Institution." He traced the rise and progress of the Institution, and made some witty comparisons between the typical characteristics of members of the electrical engineering and other professions. Dr. Gisbert Kapp (President I.E.E.) responded, and drew a parallel between the story of *La Mascotte* and electricity, ending with the moral that the latter was a good servant, but a bad master. There was such a thing as the wrong application of electricity; for instance, he thought any attempts to smelt iron out of iron ore in these islands by the use of electricity would not be a commercial success. Although the country at large benefited largely by the industrial applications of electricity, he was afraid that they themselves, like *La Mascotte*, were sometimes reduced to rags and tatters as the only reward for their efforts. Dr. Kapp next referred to the swing of competition and progress between this country and its competitors, and to what he was pleased to term the Cassandra-like attitude of a section of the electrical Press with regard to British progress. He pointed out that Great Britain had led in many processes and inventions, and made reference to the six or seven firms in this country in which it might be said that electrical forcing methods were in use, with the result that the average yield had been increased by over 30 per cent. The Right Rev. the Lord Bishop of Galloway and Glasgow, in an amusing speech, proposed "The Local Section." In replying, Mr. G. E. Tidd, the Chairman, drew attention to the advantages the Institution offered, more especially to the younger men, who, he said, should join as students without delay. Referring to the recent phenomenal fog in Glasgow, Mr. Tidd said the electrical engineers had come out well, and that every praise was due to Mr. Lackie and his assistants, who had given the gas department a good lead.

Underground Telegraph Lines.—The Underground telegraph line from London to Edinburgh was completed last week.

The Physical Society's Annual Exhibition.—This exhibition is to be held on Tuesday, the 14th inst., at the Imperial College of Science and Technology, Imperial Institute Road, South Kensington, and will be open in the afternoon from 3 to 6 p.m., and in the evening from 7 to 10 p.m. Short discourses will be delivered at 4 and 8 p.m., by Prof. C. V. Boys, F.R.S., on "Soap Bubbles," and at 9 p.m., by Prof. S. P. Thompson, F.R.S., on "Combinations of Mica and Selenite Crystals." The following firms will be exhibiting:—British Radio-Telegraph & Telephone Co., Ltd.; Cambridge Scientific Instrument Co.; Casella & Co.; A. C. Cossor, Ltd.; H. W. Cox & Co.; Elliott Bros.; Everett, Edgcumbe & Co.; Gallenkamp & Co.; Gambrell Bros.; J. J. Griffin & Sons; India Rubber, Gutta Percha, & Telegraph Works, Ltd.; Isenthal & Co.; Marconi's Wireless Telegraph Co.; Leslie Miller; Muirhead & Co.; Nalder Bros. & Co.; Nalder Bros. and Thompson; R. W. Paul; Pitkin & Co.; the Reason Manufacturing Co.; Siemens Bros. & Co., Ltd.; Synchronome Co.; Weston Electrical Instrument Co. Invitations have been issued to the Institution of Electrical Engineers, the Faraday Society, the Optical Society, and the Röntgen Society. Admission in all cases will be by ticket only, and therefore members of the societies mentioned (including also the Physical Society) desiring to attend the exhibition should apply to the Secretary of the society to which they belong.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 2nd, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

24,212/08. **Supports for Metal Filaments.** Société Française d'Incandescence par le Gaz (Système Auer). A central porcelain rod carries a series of nickel wire supports forming a helix. Fine platinum or platinum-iridium hooks are fused to the ends of the supports. These lessen the cooling of the filament by conduction, and do not melt at the high temperature attained by the filament. Two claims, one figure.

667/09. **Interior Reflector for Metal Filament Lamps.** J. Meszaros (Southfields). A hollow thin glass cylinder or cone, silvered on the interior, is supported on the central glass rod between the collars from which radiate the filament supports. The cone is thus fixed in the interior of the filament cage and reflects in all directions. The central rod is rigidly fixed to the base, but connected to the lamp pip by a spring. One claim, five figures.

2,730/09. **Tool for Removing Lamp-shade Rings.** D. L. Broadbent (Southport). A set of spring arms connected at the bottom and tending to spread outwardly, is arranged in a sleeve attached to a handle. By forcing up the handle, the sleeve slides over the arms, so that they grip the shade-ring and enable it to be turned. Three claims, three figures.

4,172/09. **Telephone Cable.** British Insulated & Helsby Cables, Ltd., W. Aitken, and C. R. Sproule. Cables for telephone switchboard work sometimes comprise 21 triple wires laid up round a cardboard core. Inductive disturbances may result from the signalling and speaking circuit wires being laid up together, and the cardboard centre is apt to absorb moisture. In an improved cable, the wires are twisted together in pairs, and these are then twisted in sets of three. Seven such sets form the core, and are passed through a former of flattened tubular section. The 21 signalling wires are laid up round this core, and the whole is then cotton-covered, foiled, and braided. One claim, one figure.

19,012/09. **Lessening Noise from Machines.** Siemens Bros. Dynamo Works, Ltd. (*Siemens-Schuckertwerke-Ges.*). The noise produced by rotors with salient poles is lessened by fitting side discs to the body of the rotor so that the poles are enclosed in a ring-shaped canal. When the cooling is not sufficient, distance pieces are placed between the discs and the yoke to provide openings for air to flow into the canal. Three claims, four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Highfield [Wiring system] 24,533/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Automatic regulation of distributing system] 345/09.

Dynamos, Motors, and Transformers: British Thomson-Houston Co. [Control of A.-C. commutator motors] 19,299/08; Allmänna Svenska Elektriska Aktiebolaget and La Cour [Regulation of polyphase commutator machines] 24,581/08; British Thomson-Houston Co. and Whitaker [Machines] 24,854/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Packings for turbine shafts] 24,936/08; British Thomson-Houston Co. (*Allgemeine Elektricitäts-Ges.*) [A.-C. machines] 10,497/09.

Electric Ignition: Cecil and Bronsdon [Ignition for combustion engines] 27,212/08; Lewis [Apparatus for igniting miners' lamps] 28,235/08.

Electrometallurgy and Electrochemistry: Langbein-Pfanhauser-Werke Akt.-Ges. [Rapid electroplating] 14,091/09.

Incandescent Lamps: Fuller [Hand-lamp] 803/09.

Instruments and Meters: Leitner [Contact voltmeters] 27,684/08.

Switchgear, Fuses, and Fittings: Dawson [Attachment of shades to glow lamps] 27,639/08; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Automatic regulating device] 345/09; Fuller [Hand-lamp] 803/09; Green [Lamp-shade carrier] 3,250/09; Flood [Switches] 5,805/09; Lake (*Cutler Hammer Manufacturing Co.*) [Snap-switches] 6,832/09; Mygatt [Shades] 8,323/09 and 10,662/09; Electric Pulley Block Co. (*Gese*) [Motor starting and reversing devices] 9,275/09; Van Daalen [Controllers] 15,203/09; Siemens Bros. Dynamo Works and Schupp [Motor starters] 16,537/09.

Telephony and Telegraphy: Conner [Telephony] 10,255/09; Higgins [Keyboard telegraphic transmitters] 14,717/09.

Traction: Hacking and Hill [Electrically operated points] 12,614/08; Carrick and Proctor [Rail-sanding gear] 1,305/09; Ayton and Crosta [Rail-grinding machine] 6,702/09; Dukesmith [Testing air-brakes] 12,968/09; Merritt and Coburn [Rail-joints] 13,954/09; Th. Goldschmidt [Rail-joint welding] 18,708/09.

Miscellaneous: Boult (*Stromberg Electric Manufacturing Co.*) [Date and time printing devices] 16,999/08; Rutherford [Signalling in mine-haulage plants] 21,693/08; Müller [Illuminated advertisements] 22,069/08; Davis, Brookes, and Harper [Diver's lamp and telephone] 26,867/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: Allgemeine Elektricitäts-Ges. [Polyphase commutator machines] 26,046/09, and [Machines] 26,146/09.

Telephony, &c.: Compagnie Générale Radiotélégraphique Carpentier Gaiffe Rochefort [Wireless telegraphy and telephony] 25,542/09; Siemens & Halske Akt.-Ges. [Printing telegraphic receivers] 25,659/09, and [Telephone exchanges] 26,269/09.

Traction: Soc. in Accomandite per l'Utilizzazione Delle Invenzioni Ing. Beer [Block signalling] 26,487/09.

Miscellaneous: De Sainte-Claire [Clutches for electric automobiles] 13,407/09; Osterburg [Suspension of lamps] 22,941/09.

Amended Specifications Published

The following amended Specifications can now be obtained.

16,968/07. **Adjustable Carbon Powder Resistance.** H. S. Martin. This patent was amended at the request of the owners, The Electrical Regulators & Economisers, Ltd. For abstract, &c., see Electrical Engineering, September 30th, 1909, p. 859, October 21st, p. 912, and November 25th, p. 1014.

4,339/08. **Magneto-Generator.** T. Wardell. The amendment was made as a consequence of opposition to grant. For particulars, see Electrical Engineering, June 24th, 1909, p. 594, and November 4th, p. 590.

Opposition to Grant of Patents

19,847/08. **Lengthening the Life of Metal Filaments.** Glühlampenwerk Anker-Ges. Opposition to the grant of this patent has been entered. The specification abstracted in Electrical Engineering, October 21st, 1909, p. 924, describes the coating of the leading-in wires or glass pedestal with a mixture of phosphorous and phosphamn. The gas evolved on heating is said to prevent disintegration of the filaments and the consequent blackening of the bulb.

21,580/08. **Flywheel Load Equaliser.** Akt.-Ges. Brown, Boveri & Cie. The grant of this patent, abstracted in Electrical Engineering, November 4th, 1909, p. 950, is opposed. A three-phase commutator motor is connected in cascade with an induction motor, to which is coupled the flywheel, and an automatic regulator is inserted in the field circuit of the commutator motor.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: British Thomson-Houston Co. (*C. P. Steinmetz*) [Mercury-vapour lamps with coloured globes] 18,083/02; A. D. Jones and Jandus Arc Lamp & Electric Co. [Clutch-feed flame arc lamps] 16,545-6/05, and [Refractory stops for supporting carbons at their tips] 16,547/05; British Thomson-Houston Co. and E. J. Murphy [Control of mechanism] 16,657/05.

Dynamos, &c.: C. J. Reed [Control of motors] 4[illegible]633/99; J. Jessen [Automatic motor-control] 16,460/05; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Self-exciting alternator] 16,518/05; Siemens Bros. & Co. (*Siemens Schuckertwerke-Ges.*) [Ventilating field coils] 16,773/05.

Electrometallurgy, &c.: R. E. Woodsmith [Air ozoniser] 17,885/03; O. Imray (*Farbwerke vorm. Meister, Lucius & Brüning*) [Electrolytic oxidation and reduction] 18,042/0[illegible]; J. R. Craig [Ozone generator] 16,681/05.

Incandescent Lamps: L. Kamm [Nernst burner] 16,[illegible]471/05.

Storage Batteries: G. K. Hartung [Plates] 16,570/[illegible]05.

Switchgear, &c.: British Thomson-Houston Co. (*J. J. Wood, U.S.A.*) [Circuit-breakers] 18,316/02; British Thomson-Houston Co. (*T. J. Johnson, U.S.A.*) [Lightning arrester] 18,323/02; British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Drum controller] 17,809/04; C. Ruzicka [Resistances] 16,631/05.

Telephony, &c.: Siemens Bros. & Co. (*Siemens & Halske Akt.-Ges.*) [Telephony] 16,878/99; H. Carbonnelle [Transmission of photographs by selenium cell apparatus] 16,796/05.

Traction: H. E. Yerbury [Automatic control of speed] 16,712/01; G. D. A. Parr and W. Binns [Electrical operation of points] 18,060/04.

Miscellaneous: J. Schmidt [Photographer's arc lamp] 14,700/00; H. W. Friedrichsen and O. Breide [Travelling electric crane] 16,384/01; C. Chevallier [Recording target] 15,322A/04; H. F. Marriott [Electrical apparatus for determining dip in bore-holes] 17,796/04 and 17,826/04.

It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.*

SUMMARY

Dr. Ludwig Mond, F.R.S., died in London last Saturday. (Page 1054.)

The latest pattern of converging-carbon flame arc lamp, introduced by the Gilbert Arc Lamp Co., has a compact feeding mechanism without any clockwork. A step-by-step feed is effected by a ratchet-wheel alternately released by two pawls. Provision for a complete release of the wheel to bring the carbons together and re-strike the arc is also made. (Page 1055.)

The fifth annual exhibition of electrical and other physical apparatus organised by the Physical Society was held on Tuesday. (Page 1056.)

Mr. G. Marconi delivered a lecture at Stockholm on the occasion of being presented with the Nobel Physics Prize. (Page 1056.)

At the meeting of the Institution of Electrical Engineers last Thursday, a determined attack was made on the Council's policy in confining the activities of the Institution to the discussion of technical matters, and refusing to allow the Institution to take its proper place as the representative body of electrical industry. Messrs. Garcke, Rutherford, Raworth, Swinton, and Rich strongly supported the condemnation of the present apathy of the Institution towards the commercial aspects of the industry, while Dr. Kapp, Mr. Mordey, and to a lesser degree Prof. S. P. Thompson, took the opposite view. There was no doubt that the general feeling of the meeting was with those who criticised the Council. The Paper which opened the way for this discussion was one by two students, Messrs. L. J. Lepine and A. R. Stelling, in which they compared the principal features of German and English manufacture and design of electrical machinery. They considered the following factors contributory to the success of German manufacture:—Commercial enterprise, good general management, close study given to schemes, large capital, and backing by banks. The two-shift system, cheap labour, and thorough specialisation, are also important factors in competition. In design England is in no way behind, in fact, in several cases the English designers are more far-seeing, and their designs more practical than those of their German competitors. (Page 1057.)

A letter from a group of members of the Bradford Engineering Society further repudiates the report published in the name of that Society on "Electrical Driving of Textile Mills."—Mr. W. R. Rawlings sends us an interesting communication regarding questions raised in Messrs. Handcock & Dykes' recent Institution Paper. (Page 1060.)

Digitized by Google

THE subject of electrical transmission gear between turbines and propellers of ships was dealt with by Mr. H. A. Mavor in a Paper read last week before the Institution of Civil Engineers, and by Mr. W. R. L Emmet in a Paper recently read in America. Mr. W. P. Durtnall also writes to us on the matter. (Page 1061.)

AT the Annual Dinner of the Institution of Electrical Engineers held on Wednesday of last week, Prof. Kapp referred to electrical engineering as an industrial mascotte, poor itself, but bringing prosperity to the other industries. He deprecated the self-humiliation of British electrical engineers, and referred to some recent "all-British" work. (Page 1062.)

THE first central battery telephone exchange in Victoria was recently inaugurated at New Windsor.—The provision of municipal tramways is under consideration in Toronto.—The Dudley and Gravesend Corporations have expressed disapproval of the proposed system of farthing tramway stages.—The question of linking up the northern and southern power stations of the County of London Electric Supply Co. has been submitted to arbitration.—The new 6,000-kw. Zoelly turbo-alternator at the Stuart Street power house of the Manchester Corporation was officially started by the Lord Mayor of Manchester last week.—A protest has been lodged in connection with the granting of the Constantinople telephone concession. (Page 1062.)

BRIDLINGTON Corporation require a 300-kw. generating set.—Extensions are contemplated at Stepney, Brighton, and Carnarvon.—Tenders are invited by the Australian Government for two wireless telegraph stations.—The Italian State Railways Department requires 50,000 metal filament lamps. (Page 1063.)

ISSUES of capital are being made by the Carmarthen Electric Supply Co. and the Rosario Electric Co. (Page 1064.)

SOME interesting life tests of Boddy lamps are given on p. 1065.

AMONG the interesting items to be found in the showrooms of the Adnil Electric Co. are a new line of D.-C. motors, a Marples' patent automatic motor-regulator for use in connection with church organs, a gear for ventilating fans enabling high-speed motors to drive fans at an efficient speed, loud-speaking telephone apparatus, and some heavy brass stampings. (Page 1065.)

THE summonses taken out by the General Electric Co. against the Welsbach Incandescent Gas Light Co. under the Merchandise Marks Act, in respect of their metal filament lamps, have been withdrawn. Although the lamps of the Welsbach Co. will continue to bear the words "Welsbach Aur," the Welsbach Co. have agreed to alter the form of their advertisements. (Page 1066.)

AN ingenious organ-blowing equipment is described. This comprises a constant-speed motor driving the bellows handle through a crank-wheel, and a variable-ratio friction gear. (Page 1066.)

PROF. E. W. Marchant and Mr. E. A. Watson have submitted a long written reply to the discussion on their Paper on high-tension transmission, read recently before the Manchester Section of the Institution of Electrical Engineers, in the course of which an interesting letter is quoted on the use of asynchronous machines in connection with water-driven exciters. (Page 1067.)

THE charge against three of the managers of the Fife Coal Co. for infringement of the Special Rules with regard to electrical plant in mines has been dismissed. (Page 1068.)

THE appeal of Messrs. John Musgrave & Sons from the decision of Mr. Justice Darling in the case brought by them against the Bradford Corporation has been dismissed. Messrs. Musgrave do not recover the sum claimed as balance of the price of a generating set, but the Corporation only receives £10 on the counter-claim, as against £1,996 claimed. The Corporation have the costs, except on one issue. (Page 1068.)

A DEVICE for improving the circulation in boilers of the cylindrical type is described on page 1068.

AMONG the specifications published by the Patent Office on Thursday last was one by J. S. Highfield for a cheap house wiring system.—A split-pole converter, in which the auxiliary poles are used both as commutating poles and for altering the voltage ratio, is covered by the British Thomson-Houston Co. and F. P. Whitaker.—Messrs. Siemens Bros. Dynamo Works and E. Schupp describe a motor-starter with auxiliary carbon contacts, in which a large area of contact and a quick movement from one auxiliary contact to the next is obtained.—A method of uniformly and rapidly electroplating sheets and rods by passing them through metal rollers, which are covered with felt saturated in the electrolyte, is patented by the Langbein-Pfanhauser Werke Akt.-Ges.—A patent by T. Laurie for a mode of supporting flexible conductors on horizontal wires, expires next Thursday, after its full life of fourteen years. (Page 1070.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, DECEMBER 16TH.

Institution of Electrical Engineers.

8 p.m. At 25 Great George Street, Westminster. (1) "Some Quantitative Measurements in Connection with Radiotelegraphy," by Dr. J. A. Fleming, F.R.S. (2) "Efficiency of Short Spark Methods of Generating Electrical Oscillations," by Dr. W. H. Eccles and A. J. Makower.

FRIDAY, DECEMBER 17TH.

Crystal Palace Co.'s School of Practical Engineering.

12 noon. Distribution of prizes by Colonel R. E. Crompton.

Institution of Mining Electrical Engineers.

4.30 p.m. Inaugural meeting at Midland Hotel, Manchester. Address by President, Mr. W. Maurice.

7 p.m. Dinner.

Northampton Institute Engineering Society.

5.45 p.m. At the Institute. Debate on "Electric Traction v. Steam Traction on Railways."

Electro-Harmonic Society.

8 p.m. Smoking Concert at Holborn Restaurant.

TUESDAY, DECEMBER 21ST.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. At the University. Discussion on "D.-C. versus A.-C. Sections for Railway Traction."

Borough Polytechnic (London).

8 p.m. Distribution of prizes by Sir H. Llewellyn Smith.

OBITUARY

Ludwig Mond

ALTHOUGH not directly connected with the electrical industry, both the personality and work of Dr. LUDWIG MOND, who passed away at his residence in Avenue Road, Regent's Park, on Saturday, at the age of seventy, had no little influence upon electrical engineering matters. As a leader in industrial chemistry, in conjunction with Sir John Brunner, he effected great advances in alkali manufacture, but his name was perhaps almost as well known from his work on the economical utilisation of fuel, and the schemes that he initiated for production and employment on a large scale of power gas. Dr. Mond at one time had hopes of applying the principle of Grove's gas battery for the production of electricity on an industrial scale, and these experiments led indirectly to chemical discoveries culminating in a successful nickel reduction process.

Dr. Mond was elected a Fellow of the Royal Society in 1891, and it was largely due to him that its international catalogue of scientific Papers was taken in hand. A further example of his benefactions to science was the foundation of presentation to the Royal Institution, and endowment of the Davy-Faraday Research Laboratory.

NEW GILBERT FLAME ARC LAMP

A NEW pattern of converging-carbon flame arc lamp has been introduced by the Gilbert Arc Lamp Co., Ltd., of Chingford. This lamp has already been installed in many large halls, open spaces, and streets in this country, and is said to have given every satisfaction. From the general view of the interior of the lamp, shown in Fig. 1, it will be noticed that the whole of the mechanism is confined to a small chamber at the very top of the lamp body, and that the two solenoids are enclosed in cases projecting below the top plate. This arrangement affords protection for the mechanism from the fumes, and reduces the length of the lamp body to that of the carbons, giving the lamp a more pleasing external appearance than is usual. The carbons have a gravity-feed, and the chief feature of the mechanism is that the clockwork or train of wheels usually employed to control the feed is dispensed with, a double pawl step-by-step escapement taking its place.

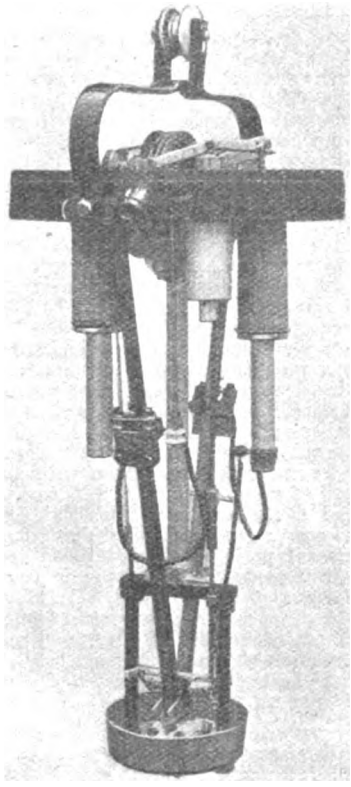

FIG. 1.—"BEACON" FLAME ARC LAMP WITH CASE AND TOP REMOVED.

Current is led to the metal-cored flame carbons through the holders, which are suspended by chains passing over a double-drum A. (See Fig. 2.) The holders slide on guide-rods, which do not, however, form part of the framework of the lamp. One rod is fixed, but the other is swung with its carbon by the sliding guide plate on the base. This plate is actuated through a bell-crank from the rocking-beam in the usual manner. There is no counter-weight to lift the carbons, but when the holders are pushed up for re-trimming the lamp, the drum winds the chains up under the influence of a spiral phosphor-bronze spring. The steel ratchet-wheel C of the escapement is on the same spindle as the chain-drum A, and is engaged by two pawls, D and E. These pawls are pivoted on the frame, and are actuated by lugs H and K on the rocking-beam. The lugs are provided with small steel wheels to avoid excessive friction. Assuming the current to be switched off, the carbons will be in contact, and the beam will be in the position shown in Fig. 2. The beam will be far down, and the lug H will press the pawl D away from the wheel to such a degree that the pawl E will also be held out, as shown in the lower inset drawing. This frees the ratchet-wheel entirely. When the circuit is closed, the series solenoid pulls up its plunger and rocks the beam, so that pawl D engages with and locks the wheel, while the link attached to the guide plate moves the swinging carbon and strikes the arc. As the arc lengthens, the series solenoid weakens and the shunt strengthens, with the result that the beam is rocked to the left. Lug H lifts pawl D, but pawl E is released by K by the same movement, and engages with the wheel as shown in the upper inset drawing. Thus the ratchet-wheel is allowed to advance only a fraction of a tooth. This feed, however, is sufficient to cause the series coil to rock the beam in the other direction, so that the lug K descends and lifts the pawl E out of engagement with the wheel. This allows the wheel to complete the advancement of one tooth, and the position is again that shown in the main view with pawl D only engaging with the wheel. On the arc

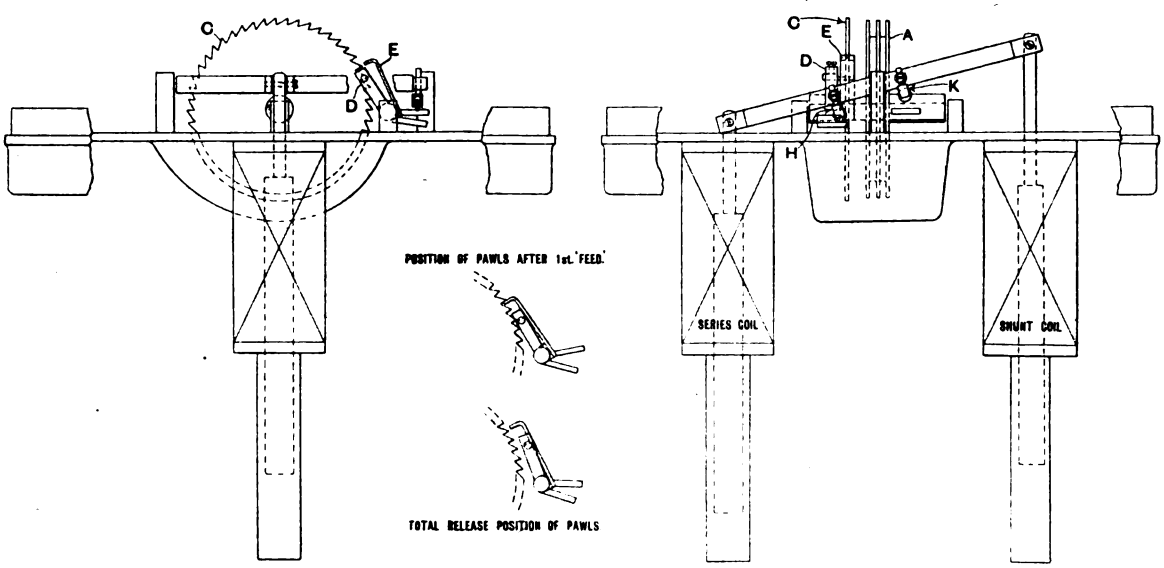

FIG. 2.—DETAILS OF MECHANISM OF "BEACON" LAMP.

Digitized by Google

lengthening again to a degree beyond that possible of compensation by a mere swinging of the carbon, the same double-feeding movement takes place. Should the first feed not be sufficient to effect a backward rocking of the beam to complete the movement, the beam will descend still further, owing to the upward pull of the shunt coil. The lug *H* will then further depress the tail of the pawl *D*, and the latter (which has a projection engaging with pawl *E*), will draw *E* back also, and cause a total release of the wheel. The carbons will then fall, touch and strike as when the lamp was first switched on. This additional feature prevents the lamp going out, due to inequalities in the carbon core, which might cause the first feed to be insufficient.

The rocking-beam is carried on knife edges, and its movement is damped by a dash-pot. A catch is provided for holding up the carbon-holders when trimming, and the ultimate release of this is ensured, as the globe cannot be put on until this has been done. A substitutional resistance, comprising a spiral of non-corrodible wire arranged on an insulating frame, can be placed in the lamp body directly under the top plate, and an automatic switch is provided for putting this in circuit when the lamp fails. This comprises a copper brush attached to the beam, which short-circuits two contact pieces when the beam sinks down to the extreme position. The shunt coil is left in circuit, and presses the brush down on the contacts. This lamp can be used both on A.-C. and D.-C. circuits, springs being interposed between the laminated cores and the beam in the former case. The lamps burn five in series on 230 volts D.-C. A 10-amp. lamp burns from 12 to 16 hours. A weak electromagnet is provided to blow the arc downwards, and this forms part of the frame, connecting the central brass pillar with the cast-iron base-plate as shown in Fig. 1. The poles of the magnet pass through brass rings in the iron plate, and this prevents a complete short-circuiting of the magnetic field. A fireclay economiser is supported in the base-plate.

THE PHYSICAL SOCIETY'S ANNUAL EXHIBITION

ON Tuesday afternoon and evening the fifth annual exhibition of scientific apparatus organised by the Physical Society was held at the Imperial College of Science, South Kensington. There was a fine collection of electrical, optical, and other physical apparatus, and though laboratory and research instruments predominated, there were a number of items of interest to the electrical engineer.

The exhibit of Messrs. Siemens Bros. & Co., Ltd., included an induction bridge, this consisting of a combined D.-C. and A.-C. Wheatstone bridge, and the range of the example shown was from large coefficients down to about 10^{-3} Henry. A high-frequency generator of the toothed-wheel inductor type for a maximum frequency of 6,000 per second was also shown. Another interesting item was a direct-reading magnetic testing outfit in which the indicating instrument has a moving coil supplied with constant current, while the strength of the magnetic circuit, consisting of the iron under test, is varied. Various laboratory instruments were also shown, including a Saladin double-mirror galvanometer for projecting a curve on a stationary photographic plate.

The India Rubber, Gutta Percha, & Telegraph Works Co., Ltd., showed a Rymer-Jones standard mica condenser. A two-tone telegraphic transmitter and a Gott fault-searcher coil for inductive signalling between a cable ship and a cable station during the making of a final joint and splice of a cable repair were also exhibited. Messrs. Muirhead & Co., Ltd., had a combined Kelvin recorder and cable relay. In this instrument a fine gold wire is stretched between the vibrator-armature and the glass siphon of the recorder and makes contact on two silver contact pins. The vibration of the wire prevents "stiction" between the wire and the contacts. A Muirhead stretched wire relay for use in the local circuits of cable relays was also shown. Messrs. Nalder Bros. & Co. exhibited a Duddell bifilar vibration galvanometer. The damping of this instrument is made as small as possible, and it can be tuned to any frequency from 100 to 1,800 periods per second by adjusting the tension and length of the vibrating wires. Using a scale distance of one metre and a frequency of 100, a deflection of 40 to 50 mm. per micro-ampere is obtainable. A Mansbridge variable self-induction standard and a new d'Arsonval galvanometer for use either as a damped or undamped instrument were also shown. Messrs. Nalder Bros. & Thompson, Ltd., had a temperature-measuring instrument consisting of a Wheatstone bridge with three arms of wire of no temperature coefficient, and one of copper, combined with a moving-coil ohmmeter. Testing sets and instruments were also shown by this firm. An exhibit by Marconi's Wireless Telegraph Co., Ltd., included an improved form of valve receiver, and the British Radio Telegraph & Telephone Co., Ltd., showed a complete receiving equipment, comprising a tuner and a detector, the latter consisting of a wound laminated cylinder of magnetic material rotating in a diametrically opposed field.

Messrs. Elliott Bros. exhibited a Harrison photometer with an attachment for measuring horizontal illumination, and a selection of instruments. Among the apparatus shown by Messrs. Everett, Edgcumbe & Co., Ltd., was a new type of rotary synchroniser in which all the windings are fixed, thus avoiding rubbing contacts, and a selection of dynamometer instruments. These latter can be calibrated with direct and used with alternating current, and can be made completely immune from disturbance by stray fields. A photometer bench for central station use and a Trotter illumination photometer were also shown. Messrs. John Griffin & Sons, Ltd., showed a representative selection of laboratory apparatus, including a Sands apparatus for the rapid electro-analytical separation of metals, and Messrs. H. W. Cox & Co., Ltd., exhibited X-ray and high-frequency apparatus.

The exhibit of the Cambridge Scientific Instrument Co., Ltd., included an improved Féry radiation photometer. A special alloy now used in the thermo-couples of these instruments enables a standard pivoted milli-voltmeter to be used in place of the more delicate suspended-coil galvanometer. The latest patterns of Duddell oscillograph and a Drysdale stroboscopic slip meter were shown, and a demonstration was given with an Abraham rheograph, arranged for projecting B.-H. curves on a screen. Messrs. Isenthal & Co. exhibited Moscicki condensers for use in wireless equipments, and also some new compact wire resistance units. Several patterns of unspillable accumulators were shown by the Lithanode Co., and the Reason Manufacturing Co. exhibited electrolytic meters and a Murday patent battery-driven clock. A phase-shifting apparatus for use in meter testing and a new potentiometer, reading from one-millionth of a volt to 18 volts, were shown by Messrs. Snell & Tinsley. The Weston Electrical Instrument Co. exhibited a selection of their well-known instruments.

WIRELESS TELEGRAPHY

MR. G. MARCONI has been awarded a share of the Nobel prize for physics, in recognition of his services in the development of wireless telegraphy. In connection with the award, Mr. Marconi delivered a lecture at Stockholm in which he gave a history of the progress of wireless telegraphy from his early experiments in Italy in 1895.

We understand that the Lepel wireless telegraph system has been brought to the notice of the Auckland, N.Z., Harbour Board, together with a suggestion that a station should be erected in time to enable the first P. & O. boat arriving there in February to be greeted by wireless telegraphy. The Lepel Company offer to give a guarantee as to the efficiency of the plant. The Auckland Harbour Board have decided to draw the attention of the Postmaster-General to the matter.

The French Chamber of Deputies has adopted a motion approving the adhesion of France to the International Radio-telegraphic Convention, 1906.

The Wimbledon Technical Institute Management Committee have decided to erect a wireless telegraph apparatus at the local technical school.

The Otley (Yorks) Council have given permission to a local electrical engineer to utilise the May-pole for the purpose of an installation of wireless telegraphy for experimental purposes.

The new Boulogne station of the French Government situate on that part of the cliff known as "La Warroquerie," is to be opened for the public service on January 2nd next. It is equipped on the Bellini-Tosi directive system, either the directive or the ordinary circular method being employable at will. The four masts are 40 metres in height, and are placed at the corners of a square of 80 metres side.

According to the *Times* Rome correspondent, the Marconi telegraphic stations erected in the Italian colonies are already giving good results. Two different systems have been now completed in Somaliland, one connecting the posts at Mogadish, Itala, Merka, and Lugh, and the other connecting Brava Giumbo and Bardera. The Merka and Mogadish line is in active use for commercial as well as official messages, both Arab and Somali traders having discovered the benefit of being able to communicate quickly by its means. The high-power stations at Mogadish and Massawa, which are to connect the two colonies of Benadir and Eritrea, are not yet in working order.

The *Liverpool Post* understands that the Mersey Docks and Harbour Board are seriously considering a proposal to install wireless telegraphic apparatus in their lighthouses and light-ships, with a central intercommunication station on the roof of the new dock offices.

THE DUTIES OF THE INSTITUTION OF ELECTRICAL ENGINEERS TO THE ELECTRICAL INDUSTRY

A PAPER by Messrs. L. J. Lepine and A. R. Stelling, entitled "Notes on Methods and Practice in the German Electrical Industry," was read at last Thursday's meeting of the Institution of Electrical Engineers, and was also discussed by the Manchester Local Section last Tuesday.

Considering first the financial aspect, the authors pointed out that prior to 1899 the industry in Germany was divided up among a number of moderate-sized firms, but financiers soon realised the advantages of amalgamation. With each of the more financially powerful firms was associated an investment company, the majority of the shares in which were held by the manufacturing company. The investment companies were enabled to obtain markets for the parent firm. The remainder of the shares in the investment company were, as a rule, held by syndicates of financiers or by banks. The principal sphere of action of the industrial banks (and deposit banks having an industrial development department) was in connection with supply companies and electric tramways or railways. When such a company was floated, the bank or investment syndicate took up or underwrote a certain number of shares. The necessary capital was obtained by the issue of bonds on the share capital of the bank and on the shares already held in other companies. The manufacturing company also took up a number of shares, shares already held being mortgaged for a purpose of obtaining the ready money. Where advances were made to companies for extensions these were redeemed later by mortgages on the new plant or by a new issue of capital.

This system readily lent itself to speculation. During 1899 and 1900 a boom in electrical engineering led to much speculative promotion of electrical schemes and exaggerated extensions. The result was an inevitable reaction, and the Dresden and Leipzig Credit Banks had to go into liquidation. Several firms had to undergo entire reconstruction, and many of the smaller firms were absorbed by the larger ones. There emerged from this period the three great combinations of Allgemeine Elektrizitäts Gesellschaft, the Siemens-Schuckert group, and Felten-Guilleaume-Lahmeyer. The amalgamated firms proceeded to strengthen their position and prevent *injurious* competition by completing certain working agreements. The result of the amalgamation and working agreements caused a steadying of prices, and an ultimate recovery of confidence. Many of the investment companies became entirely merged in manufacturing concerns, and were enabled to reduce their capital; others improved their financial position by disposing of their shares in unremunerative concerns and in the opening up of new fields.

In the improvement of the trade the material assistance afforded by financial syndicates has been of such value that during 1908 a further step in electrical finance was taken. This was the establishing of two electro-trustee banks (Elektro-treuhandbanken) under the control of the large German electrical companies. The object of these "trustee" banks is to advance to large consumers in the electrical industry the money they may require for beginning and carrying out of costly works. The capital needed for the loans is to be obtained by mortgage bonds, secured in the first place by the stocks held by the bank, and in the second place by the share capital of the latter which is to be invested in trustee stocks. As the shares, however, will most probably be retained by the electric works concerned, the entire business resolves itself into a transaction enabling these companies to raise the funds they need in order to assist and open larger credits to their customers, the formation of separate banks evidently have been decided upon as the most likely method of facilitating the placing of bonds. These facilities for obtaining cash advances are to be extended principally to municipalities and other public bodies, so that the bonds will be to all intents perfectly secure, while at the same time these authorities will be encouraged to proceed with any plans for the erection of new or the extension of old electrical plant which they may have under consideration, without the necessity of issuing new loans for that purpose.

Internal Organisation.—In the offices of the firms in question each branch of manufacture is an organisation in itself, having its own drawing office, designing, costing, and clerical staff. There are separate drawing offices for estimating purposes for transmission schemes, lighting schemes, and central station designs. A "literary" department run by University graduates is responsible for the catalogue and journalistic work. Each firm has also a foreign department which deals exclusively with inquiries from abroad, and which is in correspondence with the branch offices (outside Germany) and the subsidiary companies. The average technical employee is more highly theoretically trained than in England. All members of the technical staff go through one of the drawing offices, and they are usually bound under a contract which is all in favour of the employer. The employee agrees to publish no technical matter without the consent of his firm, to give no private tuition on technical subjects, not to divulge any methods of the firm by whom he is employed. Further, all designs which may be patented are the property of his employer. After leaving college the engineer commencing work at about twenty-four years of age receives £6 5s. a month. This increases with machine-like regularity until it reaches the maximum wage for the department.

External Organisation.—In dealing with their home trade, the German method of working up connections is thorough. Besides obtaining business by ordinary methods through their head and branch offices, they spend considerable sums of money in educating the masses. European trade is developed chiefly by means of subsidiary companies having share capitals varying from £100,000 to £600,000. These are all provided with branch offices, controlled by the subsidiary company financially, but dealing direct with the factory in technical matters. Complete staffs are maintained in the countries outside Europe, where many competitive English firms are content to employ agents.

Works and their Systems.—The machinery is most advantageously distributed with regard to light, transport, and the rotation of machining operations. Each department has its own stores, and the departments are so arranged that a minimum amount of transport is necessary to pass each unit from one stage of manufacture to the next. Automatic machinery is largely used, as are also turret lathes, but jig-work does not receive the same attention given to it by up-to-date English firms. The most striking feature in the works system is the working day. This consists of 18 hours worked in two shifts of 9 hours each with ½-hour intervals in the middle of each shift and half an hour between the two. Thus the shifts are from 7 a.m. to 4.15 p.m., and from 4.45 p.m. to 2 a.m., and overtime is an unknown quantity. The Trades' Unions have acquiesced in this system of double shift, and, moreover, are not likely ever to attack it. It is a system worthy of consideration by English firms, but the opposition of Trades' Unions would probably stand in the way of its adoption. The labour problem in Germany does not present the difficulties that it does in this country, partly on account of the different nature of the Trades' Unions and partly owing to the way in which the Government has framed legislation on labour matters. An important feature in the cheap production is the low rate of wages paid. The average wage for mechanics is 32s., and winders on high-tension stators earn 36s. a week as a maximum. Male winders of small induction motor stators and rotors earn anything up to 30s. a week. Female labour is largely employed, and females can earn higher wages than those employed in English works. Piece-work is the rule, with the "Kollonnen-system" in erecting, under which one man is given finished units, a number of assistants, and a fixed sum, out of which all wages are to be paid. As regard individual workmanship, the German electrical engineering firms do not compare favourably with the English.

General Features and Design of Machinery.—Almost all German firms insist upon the acceptance of their own specifications, and will rarely if ever depart from these. The authors recapitulate some of the principal features of German direct-current machines, and remarks that, taken all round, the English machine shows more modern principles of design, and except for slow-speed haulage motors, with which the Germans are very successful, England is in no way behind as regards design and workmanship.

The authors proceed to give a set of curves showing that the average German machines appear to be heavier than the English above 30 B.H.P., but under 30 B.H.P. there is not much difference. With regard to machines above 100 B.H.P. it was rather difficult to make a comparison owing to the fact that German makers favour slow-speed machinery, while the tendency in England is towards high speed. This variance is the result of the different engine-makers' standards in the respective countries. The German high-speed machines are built chiefly for belt driving. Regarding the electrical design, German firms used to design their machines with very large diameters and short length of core. This practice led to a large ratio of iron to copper in the armatures, the ratio of 2·7 to 1 often being reached. New designs have been brought out in which the weights of active iron have been reduced, and the

Digitized by Google

ratios of 1·8 to 1 and 2 to 1 are now more prevalent. The saturation of the teeth is carried high, 24,000 lines per square cm. being a good average maximum density.

The tendency in the design of induction motors appears to be towards long length of core and smaller diameter. Forced ventilation is becoming popular, and most end-plate type motors are designed for driving a current of air through the motor parallel to the shaft. Most German designers give a larger ratio of iron to copper than is English practice. The stator windings of small motors are usually of the threaded through type in closed insulating troughs, semi-enclosed slots being invariably used. Steel rods are used to fill out the troughs when winding. All the taping is female labour, and is very often slovenly. Large rotors are often wound with closed circuits as distinct from "squirrel-cage."

The authors were more favourably impressed by German induction motors than by direct-current motors, but consider that English designs are in no way behind those of Germany. They give a curve of weights against outputs of German and English induction motors, which shows that the German induction motors are, as a rule, lighter for their output than the corresponding English machines.

They then passed on to set forth some of the principal features in the design of typical German alternators, which do not appear to show much difference from English practice. Until recently makers did not make a standard line of medium-speed alternators for large outputs, slow-speed machines for coupling to slow-speed steam or gas engines (slow speeds being general practice among German engine-makers), and high-speed machines for coupling to water and steam turbines being the rule. Exciters are usually specially designed, and for direct-coupled units are fitted with an abnormally large number of poles for their output. Compounding of alternators is carried out by all firms even on medium-sized units.

With regard to turbo-alternators, no stator cases are made split on the horizontal centre line now, and, further, all large units are so arranged that the hot air from the stator is not delivered into the engine house, but is driven outside the building.

There are several interesting types of rotor construction, each firm having its own design. In one of these the rotor is cylindrical with a distributed winding. The core is one solid forging with the shaft, to which the teeth are attached as follows. The teeth are built up of stampings in packets of about 6 in. length, so arranged that there is a clear space through from top to bottom on the middle 2 in. The packets are riveted together, and after being ground to size the rivet heads project about ¼ in. outside the packet, so that when the packets are placed together on the core a vent space of about ½ in. is formed. The excitation coils are former wound, and while subjected to pressure each coil is enclosed in a metal casing which is soldered up, thus rendering the coils water-tight (*i.e.*, non-hygroscopic) and affording excellent mechanical protection. The coils are laid on the core and the teeth packets slid into position on either side of the coils. These teeth slide in grooves milled out along the core, the grooves being deep enough to permit a current of air to pass under the teeth to the vent spaces. The coil ends are bound down to the core body by means of banding wire wound on by a special machine under tension. Over the first banding comes a bronze sleeve and another banding on top of that. Copper wedges are driven over the windings in the slots and steel wedges are arranged in the empty slots to take up lateral pressure. These wedges when driven in press down the coils into the core with a pressure greater than the maximum pull due to centrifugal force, and they also press the teeth packets against the grooves in the core so as to form good magnetic contact. The bronze sleeve short circuits the copper wedges, which form amortisseurs.

In another design the core is built up of steel plates with the slots already punched in. These slots are unequal in width and unequally spaced, the spacing being so arranged as to give the desired flux distribution curve without having any empty slots. In cases of large outputs the whole rotor is forged out of the solid and the slots milled out. In this space the slot is very deep, with a shoulder half-way down on which a metal lining rests to support the winding. The lower half of the slot thus forms an air channel directly under the winding. The coils are wound on the rotor, each coil being separated from the following one by aluminium packing pieces. Presspahn slot insulation is used, and the coil in one slot is wound in layers, the layers being kept separate by a special compound put on hot. In addition to the aluminium packing there are L-shaped steel plates, the lower limb of the L fitting in grooves turned in the rotor hub. The interstices are all fitted with compound and a bronze ring is shrunk on over all.

Another firm adopts salient-pole rotors from four-pole upwards. They are usually built up of steel slabs (forged) approximately 3 in. thick, with forged steel pole-piece slabs dovetailed into the hub. The windings are of copper strip wound on edge and insulated with presspahn. Bronze angle pieces hold the ends of the winding, and V-shaped packing pieces hold the coils in place laterally. The ventilation is through holes drilled in the slabs.

There is much less demand for continuous-current turbo-generators than in England, and the principal variations from English practice are in the ventilation of the armature with axial ducts. The authors draw attention to the vastly greater amount of experimental work done by German manufacturing firms than by English manufacturers.

In conclusion, the authors said :—"If the English financiers and commercial leaders of the electrical industry were as enterprising and as successful as their German rivals, English manufacturers supported as they are by the superiority of their productions would not have to fear German competition in the open market."

DISCUSSION IN LONDON (December 9th).

Mr. E. Garcke said he found it necessary to speak emphatically. He was most anxious to avoid giving offence to anyone, but the importance and seriousness of the subject did not admit of anything but plain speaking. The authors' conclusions in regard to the financial and commercial aspects of the industry in Germany and England were apparently formed without cognisance of all the facts and circumstances. He wished to address himself particularly to the statements made in the concluding paragraph of the Paper. The paragraph itself was somewhat ambiguous, but the only inference he could draw from it was that they had nothing to fear from German competition provided English financiers and commercial leaders in the electrical industry did their duty. (Prof. Thompson: Hear, hear.) This view of the situation was not, in his opinion, justified, and should not have been expressed without producing the evidence on which it was based. He would unhesitatingly say that the commercial men in this country, when not held back by restrictive legislation or by that "chaos of prejudices" known as public opinion, were the most forward in the world. In regard to our particular industry, Mr. Garcke continued, we are certainly ahead, and well ahead, in the enterprise and energy of our commercial men and in the economy and efficiency with which we operate our undertakings, and the cost of production of our manufactures compares well with that of other countries; but we are behind, and sadly behind, in the profits we make and in the organisation of our industry. It is surprising how much misfortune we endure before we bring ourselves to adopt remedial measures, and meanwhile we accuse anyone who ventures to point out the need for reform as being unpatriotic and as being actuated by selfish and unworthy motives. Undoubtedly our chief trouble is that, despite our lower costs of production, we cannot under existing legislative and fiscal conditions make sufficient profits to enable us to compete with manufacturers enjoying protected home markets. The importation of foreign manufactures is, as the authors show, very large, but the competition with German firms cannot be measured merely by our exports and imports of electrical apparatus. The imports would be much larger than they are if they had not already had the effect of reducing our prices to such a level that it is no longer very remunerative to the foreigner to sell his goods to us. (Hear, hear.) Obviously our manufacturers cannot permanently subsist without profits, and should they have to give up the struggle the foreign manufacturers would then have the English market on their own terms. We have brought our costs of production down to a minimum, but prices have been reduced in a larger ratio, so that the margin has practically disappeared. If manufacturers do not make sufficient profits to cover even their standing charges, they are unable to push business, they cannot experiment with new things, and they cannot go in for publicity enterprise; neither can they send efficient travellers to foreign countries, and as we cannot offer capital a fair reward we cannot make extensions. I have been instrumental, he said, during the past twenty-five years in raising fifteen or sixteen millions of capital for this industry, and probably very much more as a fugleman. Shareholders will not be satisfied to be told that their capital has been used to produce "an industrial mascotte, comely though poor, but very willing to work for and bring prosperity to others."* Many of the difficulties under which we are labouring can be ameliorated, but to do so we must organise our forces. The reason why we are not organised is mainly because this Institution—which possesses the heart, the nerves, and the brains of the industry—has allowed its sinews to assume a condition of atrophy. (Hear, hear.) We have relied too much on the efficacy of scientific discussion while this Institution has considered it derogatory to undertake those active duties which are necessary in order to secure beneficent legislation and vigorous and healthy development. We have no organisation that can or will speak with full authority on behalf of the whole of the industry on legislative, financial, and industrial questions. I do not suggest, he concluded, that this Institution should descend from its high scientific level, but I do urge that it should abandon the erroneous belief that the scientific interests of the electrical industry can be best ad-

* A quotation from the President's speech at the Institution dinner on Wednesday night.—*Ed. E.E.*

Digitized by Google

vanced by an attitude of apathy towards the commercial aspects. (Applause.) Gentlemen, I appeal to your President, as I have done in vain to some of his predecessors, that he should give this question his earnest and serious attention during his period of office. As an instance, I would mention the Electric Lighting Acts (Amendment) Bill which has just been passed. This demonstrates the harm which is done by there being no organisation representative of the whole industry. Is it wise to attempt to divorce the commercial and technical sides of our industry? Without profits we cannot create fresh capital, and without new capital no new enterprises can be undertaken. Without capital and without profits we cannot do experimental and pioneer work, and if we do not develop we discourage our inventors and we transfer to other countries the technical initiative which, when stimulated by legitimate hope of reward in the form of renown or profit, is the foundation of all scientific progress. (Loud applause.)

The President (Dr. Gisbert Kapp) said that the Institution was not a political body, but a body of technical men and scientists, and he warned the members against the danger of bringing politics into their proceedings. The Paper was an intensely technical one—it was financial as well—but he would appeal to subsequent speakers to keep politics out of the discussion. If they did not, the Institution would descend from the high level upon which it stood. He had not stopped Mr. Garcke, because he wished to hear what he was going to say. (Hear, hear.)

Mr. W. Rutherford (Messrs. Dick, Kerr & Co.) said he was afraid he would be unable to discuss the Paper for two reasons: first, because Mr. Garcke had already made most of the remarks he himself intended to make, and secondly, because the President had put his veto on remarks of a similar character. He could only, in the circumstances, suggest for Mr. Garcke's consideration that he should carry the discussion as a sequel into the form of an interview with a representative of the leading daily Press.

Professor Silvanus P. Thompson said he was not quite sure upon what duration of experience the authors spoke in their comparison of electrical engineering in Germany and in England. It would require a very long experience and a residence of some years in Germany to be absolutely sure that all the things which they might put down as novel were really novel in the place they were seen. Personally, he was inclined to agree with the authors that there was a great deal more importance to be placed upon the question of the eighteen-hour day and the two shifts than many of them suspected. It must make an enormous difference to a manufacturer when he was full up with work to be able to employ his machinery for eighteen hours out of the twenty-four, and not have to pay overtime. However, industrial conditions differed in different parts of even the same country, and he did not think it would be quite fair to say that the conditions described in the Paper represented Germany *en bloc*. The same thing could be seen in Great Britain. The industrial conditions were not the same in London as they were in the Midlands, or in Lancashire, or on the Clyde; otherwise, why should London be complaining that there were practically no engineering works left, and that in twenty years London had ceased to be an engineering centre. Why was this? There were no tariffs to drive trade out of London into Glasgow or Birmingham, or to Rugby or to Stafford. Trade would fluctuate. Industrial conditions fluctuated. He had made the remark some years ago that manufactures were always more or less a reflex of the surroundings under which they were produced. (Mr. Garcke: Hear, hear.) Some fourteen years ago, in a Paper on arc lamps at the Society of Arts, he had said that the German, French, and Belgian lamps looked as if they were made by clockmakers, the American lamps as if they were made by sewing machine makers, and the English lamps as if they were made by engineers. He had often wondered how it was that an electrical factory had not been started in the town of Coventry, a place where there had been many manufactures, but they had drifted away for various reasons with which tariffs had nothing whatever to do. Many years ago he had been derided for advocating the introduction of 3-phase induction motors; it was stated that machines with such a small clearance between stator and rotor as was necessary were not practical. Now we could make them something like 10 per cent. better for the same money. We had had to grow this manufacture in the teeth of the opposition of industrial men, and the great commercial men, who ought at the time to have welcomed the progress of science. (Applause.) In 1898, when President of the Engineering Section of the British Association at Bristol, he had read a Paper in which he pointed out that they were still using little bi-polar machines, each with a little high-speed engine at the end of it, whilst in other countries, high speed, large diameter, multi-polar machines were being found satisfactory. He had also advocated three-phase induction motors and various other things. He was answered by a leading partner of one of the largest electrical manufacturers in this country to the effect that it was a matter of cost, and it did not pay to produce multi-polar machines; bi-polar machines were much better for their work and much cheaper, and it was better to stock continuous current machines.

Mr. J. S. Raworth said he had been prejudiced against the Paper by the conclusion arrived at in it that English financiers and commercial leaders were not as enterprising and successful as their German rivals. Mr. Garcke had been accused of making a political speech, but he did not know how on earth anyone could discuss the Paper without. In these days the very wages paid to the workmen were a matter of politics; so was the provision made for workmen's old age; and he looked upon it with very great satisfaction that the authors of the Paper had shown that the legislature in Germany had taken very great care of the working-men, and if he might be allowed to say so, also considerable care of the capitalist. (Hear, hear, and cheers.) Associated with Mr. Garcke in the early 'eighties they went into Germany; they lighted up the first public place in Berlin with arc lamps; they lighted up a big cotton mill in Berlin, and then went into Austria and lighted up the Opera of Vienna with 1,260 incandescent lamps. Then they went on to Temesvar in Hungary, and lighted the whole of the town so successfully that the Imperial Continental Gas Association was thrown out completely, and had to take their plant away. Mr. G. H. Cottam, now Borough Electrical Engineer at Hampstead, was the engineer of that station. He stayed in Temesvar until the whole business was so thoroughly successful that it was sold to the municipality. How, then, could they accuse English capitalists of not being enterprising? The reason why the electrical industry in this country had not been so successful as that in Germany was that in this country we had gas at from 1s. 9d. to 2s. 6d. per thousand, and in Germany it was 5s. per thousand, and in addition there was a tariff against us of something like 10s., but we had no tariff against them. That was the whole business in a nutshell. (Hear, hear.) He knew the conditions under which the German industry had been developed, and he knew the principal men at the head of affairs, and the conditions were exactly as stated in the Paper. They had the very highest intelligence and the very highest enterprise, and above and beyond that, when they wanted money they had only to walk into the bank and ask for it. The position of affairs, however, was exactly the reverse of what the authors stated in this latter connection. The Paper gave the idea that the manufacturers worked their businesses up, and made the banks. The actual state of affairs was that the banks built up the manufacturing companies. The banks were the father and mother of the electrical companies, and they gave them money whenever money was wanted, and they found them business when business was wanted. Further than that—and this was most important—it was impossible for private individuals in Germany to start a factory without the assistance of the banks. If they tried to do anything of the sort, the banks barred every avenue of finance, and made it impossible. Germany had cheap labour, cheap brains, protection, and big banks, and they could cut our throats whilst we were continually struggling to get small orders, and yet did work which the authors of the Paper admitted was far superior to the work turned out in Germany.

Mr. A. A. Campbell Swinton referred to the remark made by the President at the annual dinner on the previous evening, that we were not behind Germany or any other country. From a scientific point of view that was perfectly correct. But the President gave as one instance that we supplied electricity at a lower price; if we supplied electricity at a lower price, it merely meant that we were foolish. (Applause.) The real criterion to his mind was, "Did we make larger profits?" From the Paper he gathered that the latest report of one of the German investment companies showed that no supply company in which they were interested paid less than 6 per cent. dividend. He happened himself to have recently become connected with a large electrical investment company; he believed it was the largest electrical investment company dealing with the supply business in this country, and this statement made his mouth water, because no company in which he was interested paid as much as 6 per cent. There were several reasons for this miserable state of affairs. One reason—probably a minor one—was the Board of Trade returns. What private business of any description could prosper if they had to tell their competitors and their customers exactly what it cost to make the article being sold. A most important factor, however, was that insidious form of socialism, viz., municipal trading. (Applause.) If the electric supply and tramway undertakings in this country had been left to private enterprise instead of being in the hands of municipalities, the local people with money would have found them profitable undertakings, and would have looked upon electricity as a profitable investment. They would then have been ready to find money for new enterprises and manufactures in other places.

Mr. W. M. Mordey said that in his opinion the Institution was an engineering society, not a business society, nor a trade protection society. He felt that, as an institution, the only safe course to pursue was strictly to avoid all financial questions, except in so far as they were pure engineering questions, and did not show any tendency to become political questions. He did not deny that profit-making was a proper branch of engineering. In the electrical industry it was the manufacturing businesses that had done badly. Capitalists had multiplied factories to such an extent that the work was not sufficient for all, and they could not make profits. It was not correct to

Digitized by Google

state that the Institution had not done what it should in connection with the recently passed Electric Lighting Amendment Act. A committee had been at work on it, and a deputation of the council had been received by the Board of Trade. As to the supposed lack of initiative in this country, he said that the greatest advances in modern engineering of recent years, and to-day, were being made in this country and were being copied by other countries, and in concluding his remarks said that there was very little difficulty in getting money for extensions of work the first part of which had been successful. It was those who had not been successful in the work they had done, who found it difficult to get money for extensions (applause).

Mr. THEODORE RICH, referring to the remark in the Paper that electrical engineers in this country could turn out machinery cheaper and better than in other countries, wished to know why it was that in great enterprises like the Victoria Falls power scheme Englishmen had to stand aside. He thought the answer was that large questions of international competition were frequently decided by financial considerations before the technical questions were considered at all. There was no institution in this country who would say to big firms: Go to South Africa or go to South America, and we will back you up. At the present moment the financial industrial requirements of Chicago, Buenos Aires, Berlin, and Yokohama were nearer to the London money market than the English electrical industry. It was not due to the political arrangements of any party, but to the fact that English industry during the past thirty years had had obstruction—they called it regulations—unparalleled by anything in any other country in the world. In Germany one was struck with the fact that it was essentially an industrial nation. When Bismarck started to build up that nation he said it must be an industrial nation, and to do that there must be strict co-operation between the legislature and the manufacturer, the financier and local authority; and he believed that for the last forty years they had had it. In this country, if a man wished to start a railway it was the object of the local authorities' solicitors to work up an opposition; the Board of Trade seemed to try to make the construction of the railway as expensive as possible by insisting upon unnecessary safety appliances, and multiplying the capital cost by three. He differed from the view expressed in the Paper that the average German electrical engineer was better educated theoretically than the English electrical engineer. He begged to differ from this very strongly. The average German student went to a technical school, and for every hour he spent at a lecture he spent three or four hours outside amusing himself, and he left the technical college without knowing half as much of his business as the average student in this country. The result was that in Germany there was an immense mass of what he termed semi-educated men who were suitable to be automata and nothing else, and the result was as stated in the Paper, that the technical men in Germany were exceedingly poorly paid.

Mr. A. R. STELLING replied to some of the points raised in the discussion, and a hearty vote of thanks accorded to the authors of the Paper closed the proceedings.

CORRESPONDENCE

ELECTRICAL DRIVING OF TEXTILE FACTORIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Your issue of the 9th inst. contains a letter from the Council of the Bradford Engineering Society, the extraordinary contents of which require immediate correction. The words "full inquiry" and "very carefully considering," which appear respectively in this letter and in the document described as the "Report of Special Committee on Electric Driving of Textile Factories," seem to the gentlemen responsible for these publications to have a different meaning from that ordinarily connected therewith. We can only reiterate that this document has been published without our knowledge or approval, and does not represent the views of the Committee. The actual facts regarding its origin are as follows:—

The substance of the clauses on pages 5-6 and 7 was, with certain reservations, adopted by the Committee merely as a basis for a discussion at a future meeting of the Society. The matter on pages 3 and 4 (to parts of which we take strong exception) was issued after the last meeting of the Committee, and there is no justification or authority for including this as part of the Committee's report. The Council now state that a meeting took place subsequently, in which this report was finally adopted. This statement is exceedingly surprising, as the undersigned members of the Committee cannot trace having received a notice of such a meeting. In fact, we have since learned from the Secretary that the last meeting of the Committee took place on July 30th, whereas the typewritten copy as reproduced on pages 3 to 7 of the printed report was not issued until the 31st, and was not previously seen by the Committee. This disposes of the Council's statements, and of their claim to have since made a full inquiry.

Whilst waiting for the meeting of the Society, we found ourselves suddenly confronted with the broadcast press publication of the "Report," which had not, and would not, have received our signatures. In addition it is headed by an "Introduction" of an entirely biassed character, which had never even been submitted to the Committee. We therefore, reluctantly, adopted the only course open to us, *i.e.*, to dissociate ourselves publicly from this document.

The letter from the Council of the Bradford Engineering Society concludes with personal remarks, and the insinuation of trade advertisement, the taste of which is quite in keeping with the methods adopted in the publication of the "Report." In this connection it is significant that the meeting of the Council which decided on the issue of this letter consisted of eight mechanical engineers, and that the only electrical engineer on the Council did not receive any notice of the meeting.

Yours, &c., H. ELLIS, H. A. JONES, R. POHL,
T. ROLES, C. W. SALT, W. B. WOODHOUSE.

Bradford, December 10th, 1909.

THE PRESENT ASPECT OF ELECTRIC LIGHTING.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—This Paper, by Messrs. H. W. Handcock and A. H. Dykes, opened up many new and interesting points, but the one which I found a difficulty in appreciating was the information given in relation to "Typical Gas Consumers' Accounts," for at first sight I came to the conclusion that consumers did not pay as much for gas as for electricity and that the examples could not represent an average. In order to obtain some information on this point, I issued forms containing a series of questions to 200 of my firm's employees, and as they consist of mechanics and labourers the results should represent a fair average for the artisan class. I was a little disappointed, for out of the 200 forms only 51 were returned; the majority could not ascertain how much they spent, while the others were using "penny-in-the-slot meters," and did not know the total amount which passed the opening.

Of the 51 who supplied information, they represented an average over the whole of the metropolitan area, and some extended to Ealing, Wimbledon, and Enfield, &c.

I give herewith the tabulated results for the quarter ending Christmas, 1908:—

Houses or consumers	51
Number of rooms, not counting bath-room and Scullery	190
Number of gas jets	225
Number of electric lamps	31
Number of gas cookers	29
Number of oil lamps	8 rooms.

Total amount paid for quarter ending Christmas, 1908:—

	£	s.	d.
Gas lighting and cooking	38	9	10
Electric light	3	4	5
Oil	1	4	4

One consumer used oil for lighting and gas for cooking, and his bill per quarter for gas amounts to 5s. 11d., which sum is so far as I can ascertain a fair one, but rather under the average. Taking as a basis that 6s. per quarter is a fair rate for gas cookers, the foregoing works out as follows:—

Gas light per quarter, 2s. 8d. per burner.
Electric lighting, 2s. 1d. per lamp.
Oil for eight rooms, 3s. per room.

In order to ascertain if 6s. was a fair average for a gas stove, I separated the 28 gas-stove consumers from the others, and still deducting the 6s. from each, the lighting average works out at 3s. 1d., so that a mean average would be somewhere between 2s. 8d. and 3s. 1d. (say 2s. 10d.) per quarter per burner for gas lighting, a sum which far exceeded my anticipation, while with electric light the average as before given is only 2s. 1d. per lamp per quarter.

Those who are keenly interested in tariffs may find these results useful, which is my apology for taking up so much of your space.

Yours faithfully,
W. R. RAWLINGS.

82 Gloucester Road, South Kensington, S.W.

Mr. Cuthbert Hall and Marconi's Wireless Telegraph Co.—In the Court of Appeal on Tuesday, before the Master of the Rolls and Lords Justices Fletcher-Moulton and Farwell, Mr. E. Cuthbert Hall appealed against the judgment of Mr. Justice Ridley in an action for breach of contract. When Mr. Hall resigned the managing-directorship of the Marconi Co. an agreement was entered into whereby the company, as consideration, allotted him 10,000 fully paid £1 shares. The agreement also stipulated that the company should use its best endeavours to get a quotation for the shares on the Stock Exchange. Before doing so, however, the company made an issue of preference shares, and this, the plaintiff alleged, depreciated the value of his holding considerably, and for this he claimed damages. Mr. Justice Ridley held that the company had not shown unreasonable delay in securing a quotation on the Stock Exchange, this having been done in three weeks. The Court upheld this decision, and dismissed the appeal with costs. Mr. Hall argued the case in person.

ELECTRICAL PROPULSION OF SHIPS

At the meeting of the Institution of Civil Engineers on Tuesday, December 7th, a Paper entitled "Marine Propulsion by Electric Motors," by Mr. H. A. Mavor, was read. The following is an abstract of the Paper:—

At first sight it would appear that on a ship the direct connection between the power-generator and the propeller renders unnecessary the use of any intermediate transmission device, and so long as reciprocating steam-engines were the best attainable power-generators it was possible to correlate the speeds of generator and propeller so as to gain the best efficiency of each. The steam-turbine and the non-reversible internal-combustion engine introduce a new set of conditions. On land the turbine holds the field for the largest powers, and because its speed of revolution is unsuited to any ordinary mechanical direct application of power for industrial purposes, its evolution has been directly associated with electrical transmission. These turbines are many of them of the same order of magnitude as the turbines used on shipboard, and therefore a comparison of economy in the two conditions is inevitable. Among the reasons for the higher efficiency of the land turbines are:—That the engineer on land is freer than is the marine engineer to adopt a suitable speed of revolution; that the land turbine runs at approximately constant speed for all loads, and can therefore be run on the governor, rendering easier the application of superheat and augmented vacuum; that on land it is possible to subdivide the power-units to meet the conditions of varying load, and thus maintain at the smaller loads an efficiency not materially different from the efficiency at the full load of the system; that at sea change of power is directly associated with change of speed, and the whole of the power-units must always be in motion while the ship is in motion.

The proposition here made is to provide an electric equipment intermediate between the prime mover and the propeller, extending the limits of practical economy in each by modifying the restrictions which the prime mover and propeller impose upon one another, and providing that the prime mover may operate at or near the constant speed required for the attainment of maximum efficiency and full power, and that the power expended in driving machinery not required for work is reduced to a minimum or entirely eliminated. At full power all the elements of the generating plant are in full operation and the whole power resources can be concentrated on driving the ship. When full power is not required the generating plant may be shut down in sections. To accomplish these ends special motors have been designed which give the necessary changes of speed and direction and permit of the advantageous combination or elimination of the power-generators. These motors involve no new electrical principle, but simply mechanical adaptation of well-known electric designs. Alternating current alone is available for the purpose in question, and normal motors have therefore a fixed speed of rotation which is a simple multiple of the generator speed.

Two methods of speed change are proposed, each associated with a new form of motor. The principle of operation of the "Spinner" motor is that an ordinary normal motor driving the propeller at a fixed speed, and with the shaft and propeller directly connected, is so arranged as to be rotatable as a whole about the propeller-shaft axis. This rotation is accomplished by a second motor concentrically arranged outside the first, so that the main motor system may be rotated in either direction—again at a fixed speed which is a simple multiple of the generator speed—and the speed of rotation of the propeller shaft and of the propeller in the water is the algebraic sum of the rotation of the main motor and of the rotation imposed upon it by the auxiliary motor. As both motors are reversible, it will be seen that in each direction there are three speeds, viz., (1) the speed of the main motor system: the middle speed; (2) the speed of the main motor system minus the speed of the auxiliary motor system; and (3) the speed of the main motor system plus the speed of the auxiliary motor system. The combination may be designed for any three-speed ratios, and intermediate speeds are attainable by adjustment of the turbine or engine governor.

The "Multiple" motor is an ordinary squirrel-cage induction motor in all respects, except that its stator is wound with two or more independent electric circuits each associated with a separate source of supply of energy. For example, the motor may be fed from two sources of supply at 25 and 50 periods respectively, the motor windings being for 46 and 92 poles. At full power and speed both windings are in operation under their most advantageous conditions; each of these windings results in a synchronous speed of 66 revolutions per minute. When the 25-period current is supplied to the 92-pole winding the speed is 33 revolutions per minute. Either of these motors permits of one or more generators being used together in the same mechanical system without electrical connections or synchronising devices.

The author then goes on to discuss the application of electric propulsion to certain definite types of ships, and also gives diagrams illustrating the saving in space obtained. The examples worked out are as follows:—In a cargo vessel of 840 shaft-horse-power the normal reciprocating engine equipment with a single screw would weigh 570 tons for engines, boiler, and fuel. The electrical equipment, consisting of three oil-engines, three motors, and three propellers, would weigh only 270 tons, including fuel. Further, with coal at 20s. per ton and oil at 40s. per ton, the saving in fuel-cost on a total of £17 would be £5 6s. per day at full power. In a similar cargo vessel gas-engines might be used. Taking an equipment of 770 shaft-horse-power, and using three gas-engines and one multiple motor, the respective weights of the normal and proposed equipments would be 446 tons and 229 tons. The consumption of fuel shows an equally favourable comparison. A third cargo vessel, but of 1,050 shaft-horse-power, is worked out for the purpose of illustrating the application of steam turbines to the multiple motor. One plant drives the ship under normal conditions: extra power is supplied by a small turbo-generator, and is used to keep up the ship's speed in heavy or contrary weather. On a passenger vessel of, say, 16,200 shaft-horse-power, the electrical equipment permits of a subdivision of the plant, so that at ship-speeds lower than the maximum only part may be run, and that at full power. This advantage is gained without loss in full-power economy, and without additional complication.

Electric propulsion of naval vessels was dealt with in a Paper by Mr. W. L. R. Emmet at a meeting of the Society of Naval Architects and Marine Engineers held recently in New York. An abstract of this Paper appears in the *Electrical World*.

The applications were designated as the "combination drive" and the "electric drive" respectively. In the former, use is made of both electric motors and low-pressure steam turbines for driving the propeller shafts, while in the latter the propulsion is wholly by electric motors. The first of these plans has been made the subject of a proposition to the U.S. Government for one of the new battleships, the turbine part being designed by the Fore River Shipbuilding Company and the electrical part by the General Electric Company. The second plan has been applied on a small scale to two fire-boats in Chicago, and is being elaborated for application to war vessels.

In the combination drive it is proposed to use twin screws and to mount upon each propeller shaft a low-pressure turbine and an electric motor. The motor would receive energy from a generator driven by a high-pressure turbine which would exhaust through the low-pressure turbine. The adjustments would be so made that at full speed the motor would deliver two-fifths and the low-pressure turbine three-fifths of the power taken by the propeller shafts. At low speeds the low-pressure turbine would carry no load. The motors would be of the two-speed squirrel-cage induction type without provision for reversal; the low-pressure turbine would be fitted with two reversing stages similar to those that would be adopted with direct turbine drive.

In the complete electric drive, as applied specifically to naval vessels, it is proposed to mount on each propeller shaft two motors, one of which would be arranged with pole-changing switches so as to adapt it to use at lower speeds, this motor being similar in construction and performance to that proposed with the combination drive. The other motor would have only a small number of poles for use at high speeds, but would be of the wound-rotor type adapted to producing the high torque desirable in rapid changes of the ship's direction. The result of calculations are given showing that with the electric drive there would be a reduction in the machinery weight from 520 tons for the steam-turbine drive to 354 tons; a decrease in the steam consumption from 25·6 lb. to 17·8 lb. per hourly h.p.; and with the same boiler equipment, an increase in cruising range from 4,700 to 7,600 miles at 12-knot speed, or in maximum speed from 20·5 to 21·2 knots.

Mr. W. P. Durtnall has also written us a letter on the subject:—

He expresses disagreement with the Admiralty authorities and others regarding the equally good efficiency of the high-speed propeller suitable for direct coupling to a turbine to those designed for lower speeds, and asserts that in the *Lusitania* the propeller efficiency of 48 per cent. could have been increased to about 60 per cent. by a reduction in the propeller speed from 185 r.p.m. to 86 or 100 r.p.m., resulting in a saving of 13,700 h.p. He also points out the greater suitability of small-diameter high-speed turbines for use with superheated steam. Even if the efficiency of the high-speed propeller were to be increased, he thinks there would still be great advantage in the electrical method over direct coupling, as the higher propeller speed would permit of lighter motors and still higher speeds of generating plant. He considers that a more correct method of comparison lies in comparing steam used per ton of displacement per mile rather than per shaft-horse-power hour.

ANNUAL DINNER OF THE INSTITUTION OF ELECTRICAL ENGINEERS

THE annual dinner of the Institution of Electrical Engineers was held on Wednesday, December 8th, at the Hotel Cecil. There was a total attendance of about 290 members and guests, and in addition to the speakers mentioned below, the following were present: Lord Strathcona, Sir Douglas Powell, Sir H. H. Cunynghame, Mr. C. E. Spagnoletti, Major-General Sir A. E. Turner, Sir T. E. Thorpe, Sir Philip Magnus, M.P., Dr. R. T. Glazebrook, Sir Robert Hunter, Sir E. G. Burls, Mr. R. K. Gray, Prof. W. C. Unwin, Prof. W. Grylls Adams, Mr. J. Swinburne, Dr. B. A. Whitelegge, Mr. H. T. Butlin.

Sir WILLIAM WHITE, in proposing the toast of the Institution, referred to the rapid growth both in respect of numbers and importance, and congratulated the Council on the satisfactory working of the system of Local Sections. As a representative of the Institution of Civil Engineers, he said that it had been a great pleasure both to the Council and members that they had been able to assist the Institution. Civil and mechanical engineers envied their electrical brethren for the unrivalled opportunities they had.

The President, Dr. GISBERT KAPP, replied to the toast, and referred to electrical engineering as an industrial mascotte, comely, though poor, but very willing to work for and bring prosperity to others. The staple industries of England were old-established and strong, and their leaders had thought that they could do without new helps. It was an excellent thing that the old Universities were recognising the importance of engineering, as the men they turned out to be leaders of industries would be progressive and appreciative of the fact that applied science can increase the earning power of other industries. Electrical engineers, he said, tell themselves—that does not matter, but they tell others, and that does matter—that we are behindhand. Surely it was not to the advantage of the industry to shout out, "Look how very bad we are." There were, he said, about one million kilowatts in machines installed in stations in this country, and only about 8 per cent. were of foreign make. Direct driving, the use of storage batteries, and the turbo-generator were originated in England, and the first electric railway was constructed in Ireland. One could get better value for one's money in electrical machinery in England. Even in power transmission, we might be said to be a little ahead, from an industrial point of view. At the Kinlochleven power station, there was 30,000 h.p. of British-made plant and accessories, and at the Bilston works there were a gas-engine generating plant and two electrically-driven rolling mills of pure British design and manufacture. The quarter-million horse-power which Mr. Merz had calculated was available in the waste gases of coke ovens in the North of England was of far more value than an equal amount of water power, as the capital cost of hydraulic works was so high. By agreements between the coke-oven owners and the supply company, power was supplied at lower rates in the Newcastle district than anywhere in the world. Finally, Dr. Kapp referred to the work of Sir Oliver Lodge and his colleagues in connection with the stimulation of plant and vegetable growth by the direct application of the electric discharge, and to the possible extensive use of artificial fertilisers produced electrically from atmospheric nitrogen.

Prof. SILVANUS P. THOMPSON, in proposing "Science and Industries," pointed out how unimportant a science was if it did not ramify into the several branches of industry, and then referred briefly to the careers and work of Sir Joseph Larmor and Mr. Aspinall, who were to respond to the toast. The former as a professor of mathematics represented science in its most perfect form ,and the latter had done great things in mechanical and electrical engineering. The Lancashire and Yorkshire Railway Co. was to be congratulated on having put the management and development of their traffic into the hands of a scientifically trained engineer and not a purely commercial man.

Prof. JOSEPH LARMOR (Secretary of the Royal Society) emphasised the close connection between science and engineering, and said that science pointed the way to the promised land, and the engineer took possession. In concluding, he said that he would like to express how much pure scientists were indebted to the Institution for its share in the publication of science abstracts.

Mr. J. A. F. ASPINALL (President of the Institution of Mechanical Engineers) expressed the opinion that British engineering students were as well trained as any in Europe, but emphasised the importance of languages. Men who were sent out by manufacturers should be able to talk the language of the people they went amongst. Our trade was being taken away on account of the inefficiency of our commercial men. Referring to the introduction of electric traction on main lines, he said that each small section of line would have to be considered separately; it would not be a commercial success to electrify at once over large areas. Finally, he pleaded for co-operation between electrical and mechanical engineers; that only would enable us to retain our position in the world's markets.

The toast of the "Guests" was proposed by Sir John Gavey, C.B., and responded to by Colonel Sir Charles Euan-Smith,

LOCAL NOTES

AUSTRALIA: *Victoria: C.B. Telephone Exchange.*—The first example in Victoria of a central battery telephone exchange will shortly be opened at the New Windsor Telephone Exchange. The buildings have cost about £8,000, and the equipment has been supplied by the Western Electric Co. The initial capacity of the exchange is 3,000 subscribers, but space is available for doubling this capacity.

Adelaide: Tramway Plant.—When the first section of Adelaide Tramway Trust tramways were opened, the current was supplied by the Adelaide Electric Supply Co. The power-house of the Trust, however, has now been completed, and contains three 1,500-kw. turbo-alternators. The turbines are of the Parsons type, the voltage being 11,000, and the frequency 25 cycles per second. The high-tension switchgear has been supplied by Messrs. Reyrolle, of Hebburn-on-Tyne. Sea water will be used for the condensers, and Lea recorders have been installed.

BISHOP'S STORTFORD: *Electric Lighting.*—The Council are promoting a Bill in the next session of Parliament for an extension of time for laying electric lighting mains under their Electric Lighting Order of 1905.

CANADA: *Edmonton: Electric Supply.*—The municipal electricity works were put into operation last week.

Toronto: Municipal Tramways.—A matter upon which voting will take place at the next municipal elections on January 1st is the provision of municipal electric tramways.

CHELTENHAM: *Supply of Service Cable.*—The Corporation have decided to supply 60 ft. of service cable, free of charge, to consumers.

DUDLEY: *The "Fair Fare" System.*—The new system of fares which is to be introduced by the British Electric Traction Co. on its various undertakings on January 1st, was discussed at the last meeting of the Town Council. It was complained by one Councillor that as the result of careful inquiries he found that at Dudley the stages would be so fixed as to increase, in many cases, the fares by one-half. Other Councillors, however, took the view that if the effect of the farthing stages would increase the fares to anything like this extent, public opinion would quickly compel the abandonment of the system. The Council decided to see the effect of the system before taking any action.

EDINBURGH: *New Condensing Plant.*—Before committing themselves to a decision as to introducing condensing plant at their two power houses, of which particulars have been given in our last two issues, the Corporation have decided to send a deputation to London and Birmingham to inspect plants working there. Mr. F. A. Newington, the City Electrical Engineer, will accompany the deputation.

FAREHAM: *Electric Lighting.*—The consulting engineers to the Council, Messrs. May & Hawes, report that the electricity works are practically completed.

GRAVESEND: *The "Fair Fare" System.*—The Corporation are protesting against the introduction of the British Electric Traction Co.'s "fair fare" system on the ground that it will involve an increase in the fares now charged.

ISLE OF WIGHT: *Electric Traction.*—A conference was held last week concerning the proposed scheme, for the electrification of the railway system in the Isle of Wight. The conference approved of the proposals put forward by certain private promoters, but adjourned consideration of the details until the terms have been fully ascertained.

LEEDS: *Damages for Tramcar Accident.*—At the Leeds Assizes on Monday, Harold Hufton, a hotel servant of Huddersfield, was awarded £100 damages for personal injuries incurred on a tramcar belonging to the Leeds Corporation.

LONDON: *London County Council: Invention by an Official.*—Mr. W. E. Ireland, rolling stock superintendent in the Tramway Department, has been granted permission to take out a patent for a new dust- and oil-guard for use with tramways and railway rolling stock, axle boxes, &c.

City of London: County of London Co.'s Mains.—In connection with the dispute between the County of London Electric Supply Co. and the City of London Corporation with regard to laying mains across London Bridge, and through the City, for the purpose of connecting their northern and southern power houses, the company have submitted the matter for arbitration under the London Electric Supply Act, 1908. The City

Digitized by Google

authorities claim that they have absolute jurisdiction over the City bridges.

MANCHESTER: *Starting of New Generating Plant.*—On Friday the Lord Mayor of Manchester started the new 6,000-kw. Zoelly turbo-alternator set at the Stuart Street power house. We published an illustrated description of this set in our issue for October 28th, and some further information in our issue for November 18th.

MORLEY: *Electric Lighting Charges.*—A recommendation of the Electricity Committee to increase the charge for electricity for lighting purposes from 5d. to 6d. has been adopted.

OLDHAM: *Electric Supply.*—The Lancashire Electric Power Co. have agreed to the Corporation supplying electricity to the urban districts of Crompton, Royton, Chadderton, and Lees on condition that no supply exceeding 50 h.p. is given without special permission from the company.

PEMBROKE: *Electric Lighting Surcharges.*—The Local Government Board auditor has disallowed the sum of £13 3s. in respect of expenditure upon an electrical exhibition held under the direction of the Electricity Department in June, 1908. In view of the fact that the auditor points out that the electric lighting undertaking has steadily expanded, and that the exhibition was held in order to develop the business, the Council have passed a resolution asking the Local Government Board to disallow or remit the surcharges in question. The surcharges have been made upon the Councillors who signed the cheques for the expenditure in question.

SALTBURN: *Electric Supply.*—The Council are inquiring of the Cleveland & Durham Electric Supply Co. their terms for supplying electricity in bulk.

TURKEY: *Telephone Concession.*—It is stated that the Austrian Telegraph Co., which sent in tenders for the telephone concession in Constantinople, has lodged a protest with the Ottoman Government against the grant of the concession to the syndicate consisting of English, American, and French firms.

WESTON-SUPER-MARE: *Proposed Light Railways.*—The Council have decided to oppose the application of the Weston-super-Mare Junction Railway Co. for an Order authorising the construction of light railways in the district.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BRIDLINGTON.—The Corporation require a 300-kw. steam dynamo (either reciprocating engine or mixed pressure turbine), together with switchboard and pipe work. Particulars from the Borough Electrical Engineer, and tenders by January 1st.

BRIGHTON.—Mr. J. Christie, the Borough Electrical Engineer, reports that the peak load at Southwick daily reaches the combined full-rated capacity of three of the four turbines installed, and recommends the purchase of a fifth set of 3,000-kw. capacity. This extension will involve additions to the condenser plant and circulating system, and the additional high-tension switchgear required will necessitate structural alterations. The probable capital expenditure is put at £14,500 for the new turbine and accessories at Southwick, and £3,500 at the North Road sub-station. The Electricity Committee recommend that the Electrical Engineer's proposals be approved; the Finance Committee have no objections to offer. It is anticipated that the new turbine can be operated without additional boiler power.

CARNARVON.—The National Electric Construction Co., who operate the electricity undertaking here under an agreement by which the Corporation find the necessary capital, have presented a report in which they recommend further borrowings for extensions. They also recommend the adoption of street electric lamps at an estimated capital cost of £400, and an annual cost of £150.

LONDON: *Stepney.*—The Borough Council have adopted the proposals of the electrical engineer and manager for the expenditure of £40,500 for additional plant at the Blyth's Wharf, and Osborn Street generating stations, and the Wapping sub-station.

Miscellaneous

AUSTRALIA.—Tenders are invited for the supply and erection of two wireless telegraph installations, one at Sydney and one at Fremantle. Tenders must include alternative quotations for stations with a range of 500 miles, 750 miles, and 1,000 miles. Tenders to the secretary, Postmaster-General's Department, Melbourne, accompanied by a deposit of £100, by February 22nd, 1910, and particulars from the Commonwealth Office, 72 Victoria Street, London, S.W.

BELFAST.—Tenders are invited by the Tramways Committee for the supply of bases, collars, finials, and brackets for tramway poles. Particulars from the City Electrical Engineer, and tenders to the Town Clerk by December 20th.

CARLISLE.—Tenders are invited for the supply and erection of an overhead electric line, complete with poles, &c., of about 8,000 yards of wire. Particulars from the City Electrical Engineer, to whom tenders by December 24th.

CHATHAM.—Tenders are invited by December 22nd for the supply of Osram lamps to the Corporation. Particulars from the Borough Surveyor's Office.

GRIMSBY.—The Public Lighting Committee have decided in favour of borrowing £2,000, so that the street lighting may be undertaken by metallic filament lamps in all streets where electric mains are laid, and that the existing arc lighting be brought up to date by the introduction of flame arcs.

LONDON: *London County Council.*—The Highways Committee recommend an expenditure of £200 upon lowering gear for arc lamps at car sheds.

A 2 cwt. electrically-driven power hammer is to be installed at the Greenwich Generating Station.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.E.—Lunacy wards at Infirmary, Homerton, N.E. (£1,988). Architect, W. W. Finch, 76 Finsbury Pavement, E.C.

S.E.—Building on site of London & South-Western Bank and site adjoining, New Cross Gate, S.E. Architect, C. G. Miller, 65 Chancery Lane, W.C.

School, Sherington Road, Greenwich, S.E. (£13,212). Builders, W. Johnson & Co., Ltd., Wandsworth Common, S.W.

E.—Manual training centre, Union Street, Poplar, E. Builder, C. R. Roberts & Co., 138 St. Paul's Road, N.

Cinematograph Theatre, Stratford, E. G. Wigley & Sons, agents, 9 Regent Street, W.

W.C.—Tenders are invited for the electric wiring and fitting for lighting and power of the new building of the Institution of Electrical Engineers, Victoria Embankment. (See an advertisement on another page.)

PROVINCES.

BARNSLEY.—Grammar School, Shaw Lane (£12,795). Architects, Crouch, Butler & Savage, 39 Newhall Street, Birmingham. Builder, W. R. Unwin, Ecclesfield, Sheffield.

BIRMINGHAM.—New church, Newtown Row. Rev. T. S. Dennison, St. Stephen's, Newtown Row.

BOOTLE.—Theatre, Stanley Road (£18,000). H. Pennington, Pennington Estate Co., Bootle.

BRADFORD.—Additions to Argyle Mills (£5,000). Architects, T. Baker & Sons, 15 Bank Street, Bradford.

COLCHESTER.—Tuberculous hospital. Committee of the Eastern Counties Asylum for Imbeciles, Colchester.

COVENTRY.—Warehouse, Upper York Street (£2,455). Architects, Tait & Herbert, 18 and 28 Friar Lane, Leicester.

DARLINGTON.—High school (£12,000). Architect, W. Rushworth, Shire Hall, Durham.

EPSOM.—Nurses' Home (£1,870). Architect, Mr. Williams, c/o Clerk to the Guardians.

JARROW.—Concert hall. Architects, Barnes & Burton, 6 Jesmond Dene Road, Jarrow.

LINCOLN.—Children's Home. Clerk, Lincoln Board of Guardians.

NEWTON ABBOTT.—Post office. Architects, Rowell, Son & Locke, Newton Abbott. Builder, H. Mills, Newton Abbott.

School, Wolborough (£2,825). County architect, P. Morris, 1 Richmond Road, Exeter. Builders, Bovey & Sons, Torquay.

NOTTINGHAM.—Public baths (£10,000). Architect, F. B. Lewis, Guildhall, Nottingham.

PLYMOUTH.—Roman Catholic Church, junction of Home Park Avenue and Holland Road. Bishop of Plymouth.

STOCKPORT.—Bank premises. Builder, R. Carlyle, Old Trafford, Manchester.

STRETFORD (MANCHESTER).—Mill, Trafford Park, for John Greenwood & Sons.

TEIGNMOUTH.—School, Exeter Road (£4,100). County architect, P. Morris, 1 Richmond Road, Exeter. Builder, F. J. Badcock, Ashburton.

WINCHESTER.—School. City Surveyor, Guildhall.

Telegraph Traffic.—The Bagdad-Bassorah line was restored on 7th inst.—The French Cable Co.'s cable between Paramaribo and Cayenne was down on the same day, and it became necessary to send cables *via* Salinas. A break also occurred in the line between Teheran and Hanekine, at a spot situated near Hamadan and Kernan. The cable between Kartal and Nagara was on the active list once more on the 8th inst. On the following day the cable between Bathurst and Bissao gave out, as well as the Bagdad-Bassorah land line.—After hard work the Jamaica Government managed to restore all their land lines damaged by floods on the 9th inst.—The 10th inst. brought news of delay to Melange, Dondo, Novo-re-Dondo, and Bailundo, in the province of Angola.—Two days later the French Co. managed to repair their cable between Martinique and Puerto Plata, which had broken down on the 7th ultimo. Their West Indian cables continue to give trouble where they land on the Guiana coast. The Bagdad and Bassorah line was repaired and again broke down on the 13th inst. The line between Rome and Constantinople failed on the same day.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

BRISTOL.—The Council have accepted the tender of the Bristol Electrical Co. at £129 18s. 6d. for the electric lighting of Alexandra School.

LONDON: *London County Council.*—The Highways Committee recommends that the provision of the overhead equipment for the tramways in Lea Bridge Road be placed with Messrs. Dick, Kerr & Co., Ltd.; the ducts are to be supplied by Messrs. Reid Bros., switchgear by Messrs. Johnson & Phillips, and low-tension cables by the British Insulated & Helsby Cables, Ltd. All these are extensions of existing contracts.

The tender of Messrs. H. G. Mayer & Co. has been accepted by the Stores Committee for the supply of electric carbons.

The following tenders have been accepted by the Stores Committee for the supply of electric lamps:—Cryselco, Ltd.; Edison & Swan United Electric Light Co., Ltd.; Maxim Lamp Works; Pope's Electric Lamp Co., Ltd.; Siemens Bros. Dynamo Works, Ltd.

LUTON.—The tender of Messrs. Macintosh & Co., Ltd., of London, has been accepted for the supply of cables during the twelve months ending November 11th, 1910.

PLYMOUTH.—The Town Council have entered into a fresh contract with the Tudor Accumulator Co., Ltd., at £280 per annum for 10 years for the maintainance of the batteries at the Prince Rock station and at the Armada Street sub-station. The agreement may be terminated in five years in the event of the Council desiring to dispense with the batteries at Prince Rock. The combined sums at present paid for maintenance amount to £319 per annum.

STRETFORD.—The Council have accepted offers of the British Westinghouse Co. and the Oliver Co. to each supply on approval a set of ten arc lamps for six months.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f., port of arrival, quoted on Tuesday night, was £61 10s. to £62 per ton (last week, £60 15s. to £61 5s.).

AGENCY.—The Electric Construction Co., Ltd., have appointed Messrs. Fyfe, Wilson & Co., 145 Bath Street, Glasgow, to represent them in Scotland, with the exception of collieries. For colliery work they will be represented, as heretofore, by Messrs. Hunter & Jack, 101 St. Vincent Street, Glasgow.

The agency for the sale of Messrs. B. Paege & Co.'s special insulating varnishes and paints for electrical purposes hitherto carried on by Mr. A. E. Ammon, 52 Chapel Street, Blackfriars, Manchester, has been transferred to Messrs. G. Braulik, 8 Lambeth Hill, Queen Victoria Street, London, E.C. This firm carry a stock in London in bulk, and also in half-gallon and larger tins.

The Adnil Electric Co., Ltd., Adnil Buildings, Artillery Lane, London, E.C., have appointed Mr. James Turnbull, of 3 New Street, Birmingham, agent for the whole of the Birmingham district, including the counties of Warwickshire, Worcestershire, Shropshire, and Staffordshire.

CANADIAN AGENCIES WANTED.—A London firm manufacturing electric cranes, &c., desires to open up business in Canada.

A London firm manufacturing transformer sheets, dynamo sheets, blooms for magnets, magnet steel, mild steel castings, and stampings for electrical purposes, is desirous of entering into negotiations with Canadian importers of such goods.

DISSOLUTION OF PARTNERSHIP.—The partnership between H. H. Berry and E. Skinner, electrical engineers, &c., 78 Upper Thames Street, London, has been dissolved. The business will be continued under the same name by Mr. H. H. Berry

RAWLINGS BROS.' CONVERSAZIONE.—The directors of Messrs. Rawlings Bros., Ltd., of Gloucester Road, South Kensington, gave a conversazione on Saturday evening to their employees and their wives and friends. About 400 persons met at the Cabin's Restaurant, Caxton House, Westminster, and a thoroughly enjoyable time was spent.

Birmingham and District Electric Club.—At the annual meeting, on the 11th inst., the following officers were appointed:—*President*, Mr. G. O. Donovan; *Vice-Presidents*, Messrs. F. W. Foster and T. H. Hunter; *Hon. Treasurer*, Mr. E. A. Morgan; and *Hon. Secretary*, Mr. W. G. L. Riddle.

Dispute re a Colliery Electrical Plant.—At the Swansea Town Hall, before Mr. E. J. Pollock, as official referee, a case was commenced last week, in which the Electrical Co., Ltd., are suing Messrs. O. H. Thomas, Son & Co., proprietors of the Llynvi Valley Colliery, near Maesteg, for the recovery of £3,100 for electrical plant installed. The defendants counterclaimed for £50,100 for damage alleged to have been sustained in consequence of obstruction by the electrical machinery, and also by unreasonable delay in supplying an electric pump. We shall give a fuller report of the case in a future issue. The action, which has been continued throughout the week, has been transferred to London.

MISCELLANEOUS CITY NOTES

ROSARIO ELECTRIC CO.—Subscriptions are invited by today for an issue of 20,000 ordinary shares of £5 each at par.

CARMARTHEN ELECTRIC SUPPLY CO.—Subscriptions are invited until Monday for an issue at par of 5,000 £1 preference shares, and 5,000 £1 ordinary shares. The objects of the company are to supply electrical energy in Carmarthen under a Provisional Order transferred by Messrs. Crompton & Co.

WESTERN TELEGRAPH CO.—The directors have declared the first quarterly interim dividend of three shillings per share, free of income tax, for the year ending June 30th, 1910, being at the rate of 6 per cent. per annum.

COMPANIES' MEETINGS AND REPORTS

DORMAN, LONG & CO.—At the annual meeting last week it was announced that a new electrical mill had been started, and that another was proposed. Mr. A. J. Dorman, who presided, said that, having regard to the large demand for bars and the increasing use of ferro-concrete, the directors were confident that these extensions would prove of great value to the company.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—At the annual meeting on Thursday, the report and accounts given in our issue for December 2nd were adopted. Mr. R. M. Horne-Payne, chairman of the company, referring to the threatened competition within the company's area, stated that they viewed this with complacency, as it was in connection with a scheme for the development of some water powers which was offered to the company, but which they declined.

PROVINCIAL TRAMWAYS CO.—At the annual meeting last Thursday, the report and accounts given in our last issue were adopted. The chairman, Mr. Andrew Beattie, stated that the percentage of cost to gross revenue in the case of their tramways was lower than that of any company or corporation in the United Kingdom, it being only 55 per cent.

ADELAIDE ELECTRIC SUPPLY CO.—At the annual meeting on Monday last week, the report and accounts given in our last issue were adopted.

BLACKPOOL & LYTHAM TRAMWAYS.—At the annual meeting last week the report and accounts were adopted. During the year, the receipts amounted to about £3,600. The Chairman stated that he did not know when the ordinary shareholders would get any dividend, for £13,000 was owing as interest on preference shares, and £26,353 on debentures. When the present lease ran out he did not think there would be any difficulty in getting further powers from the Corporation. They had made satisfactory terms with St. Anne's Council for electric lighting.

INDIA RUBBER, GUTTA PERCHA & TELEGRAPH WORKS CO.—At the annual meeting on Tuesday, the report and accounts given in our last issue were adopted.

APPOINTMENTS AND PERSONAL NOTES

Mr. T. L. Miller has been re-appointed consulting engineer to the Stretford electricity undertaking for one year at a fee of twenty-five guineas.

Dr. Alexander Russell, Principal of the Electrical Standardising, Testing, and Training Institution, has been appointed by the Board of Trade electrical inspector under the Willesden Electric Lighting Order, 1898.

Mr. H. A. Kell, chief assistant and electrical engineer at Luton, has been granted an increase of salary from £117 to £140 per annum.

The Northampton Polytechnic Institute require an Associate Head of the Department of Electrical Engineering and Applied Physics (see an advertisement on another page).

Electrobus Co. and its Batteries.—In the Court of Appeal, before Lord Justices Vaughan-Williams, Buckley, and Kennedy, on Thursday, Dr. Lehwess appealed against a judgment of Mr. Justice Phillimore in which Mr. C. A. Gould was granted damages to the value of £2,528 15s. for breach of contract. We reported the case fully in our issue for May 27th, p. 448. Briefly the facts are that Dr. Lehwess agreed to form an English Gould Storage Battery Co., Ltd., and to secure that the London Electrobus Co., Ltd., would purchase certain batteries on their passing some agreed tests. This company was duly formed, and certain batteries handed on to it. Mr. Gould's case was that Dr. Lehwess, finding difficulty in inducing the Electrobus Co. to take over the batteries, purposely put obstacles in the way of the necessary tests being carried out, and that in consequence the date upon which the batteries should have been handed over to the Electrobus Co., or rejected as unfit, according to the result of the tests, was allowed to pass by. The batteries had been in constant use meanwhile, and the value had considerably depreciated. Yesterday the Court ordered a new trial, principally on the ground that the assessment of the damages was made upon insufficient evidence.

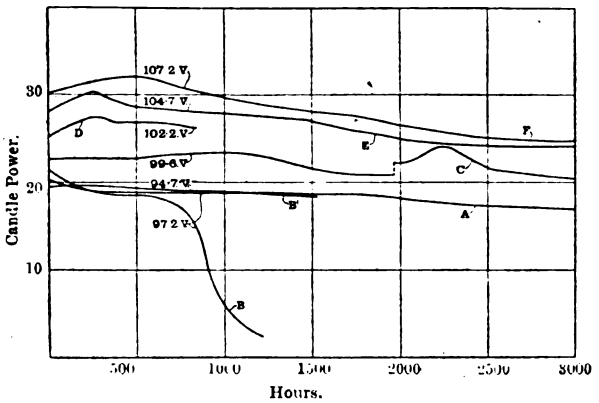
SOME INTERESTING LAMP TESTS



We publiished in our last issue (p. 1,047) some tests of metal filament lamps, which were given in a Paper read by Mr. F. H. R. Lavender before the Birmingham Section of the Institution of Electrical Engineers. In these the various lamps tested were distinguished only by numbers. Messrs. G. M. Boddy & Co. inform us that their lamps were those indicated as Set 3 in the table and curves given in the Paper, and have sent us some additional particulars and life curves concerning them.

The lamps were rated at 100 volts and 32 watts, and were run continuously at the pressures given in the table below :—

Set 3.

Lamp.	Voltage	Life in hours.
A	94·7	3.000
B	97·2	1.225
B'	97·2	1,500
C	99·6	3,000
D	102·2	850
E	104·7	3.000
F	107·2	3.000

The curve shows the drop in candle-power with life, which, except in the case of one of the six lamps tested, is practically

negligible during the first 1,000 hours. Curve C is interesting, the filament fractured after 1,970 hours, but was welded together again.

THE ADNIL ELECTRIC CO.'S SHOW-ROOMS

In some quarters there seems to have been an impression that the firm of Marples, Leach & Co., Ltd., who are the agents in this country for the Bergmann Co., and other manufacturers, has entirely gone out of existence. We are informed that this is far from being the case. The firm, we understand, had found that their capital had become inadequate to cope with the large extension of their business, and it was decided to go into voluntary liquidation, and to reconstruct the business as the "Adnil Electric Co., Ltd." Messrs. Bergmann have taken a larger interest in the new company than in the old one, and both Mr. R. A. Marples and Mr. S. G. Leach are financially interested in the results of the new company, remain as managers and control practically the same staff as before.

We were invited to inspect the firm's show-rooms in Artillery Place, E.C., last week. A representative collection of A.C. and D.C. motors includes a new line of two-pole D.C. motors of capacities ranging up to 6 h.p. Single-, two-, and three-phase motors are shown, and those above 5 h.p. have a device for short-circuiting the rotor slip-rings when up to speed. A small ½ h.p. motor represents a line of single-phase motors which can be obtained from 1/6 h.p. to 40 h.p. capacity. These are series-wound commutator motors, which can start on an overload. They have a centrifugal device to lift the brushes automatically, and to place a short-circuiting ring on the commutator when the synchronous speed is reached. The switchgear exhibited includes a liquid starter, representing a line ranging from 15 h.p. upwards, and especially adapted for D.C. or A.C. motors on extra heavy work, such as rolling mills.

A novelty shown is Mr. Marples' patent church-organ motor regulator. In this system, the D.C. motor drives a three-crank shaft operating three bellows, which feed into a reservoir in the usual manner. A wire rope attached to the top of the air reservoir passes partly round, and is fixed to a pulley; another pulley, fixed to and concentric with the first, supports a weight. Attached to the pulleys is a switch arm which works on a ring of contacts. When the reservoir is empty the switch arm is in the starting position. To start up, the organist closes a small switch at the console, which switches on the motor. As the reservoir fills, the top rises, and the switch arm moves round cutting out the starting resistance. After this, the arm is pulled round on a strip contact with the motor running at full speed until the reservoir is nearly full. Any further rise of the reservoir top puts resistance in series with the motor as the switch arm continues to move over a second row of contacts, gradually inserting resistance until, when the reservoir is full, so much resistance is in series that the motor stops, though it is still in circuit. Should the reservoir top fall, the arm goes back, resistance is cut out, and the motor starts up again. While the organ is being used, the arm moves backwards and forwards on this second row of contacts, and keeps the reservoir full. On switching off the motor, the arm returns to the starting position as the

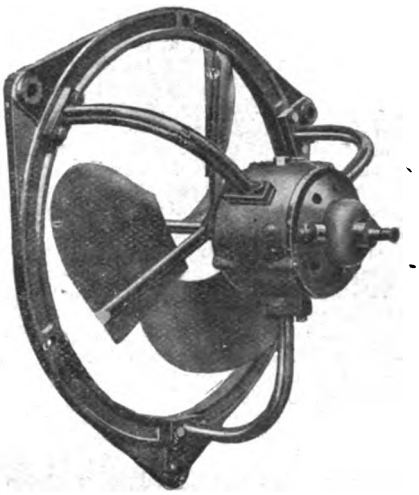


Fig. 1.—"Blizzard" Fan.

reservoir top falls. In the case of a single-phase supply, a continuously running motor-blower is generally employed, escape valves in the reservoir preventing the pressure from exceeding the normal. An alternative method for a single-phase supply is to drive the bellows shaft through a fast and loose pulley with a striking gear operated by the rise and fall of the reservoir top.

The ventilating fans shown include the "Blizzard" fan, illustrated in Fig. 1. This has a new design of blade especially adapted for moving large quantities of air, and is said to have a very high efficiency. Another novelty is a small geared fan, illustrated in Fig. 2. A rubber-covered wheel on the shaft of a small high-speed motor bears against the inner surface of an aluminium ring, to which is attached the fan

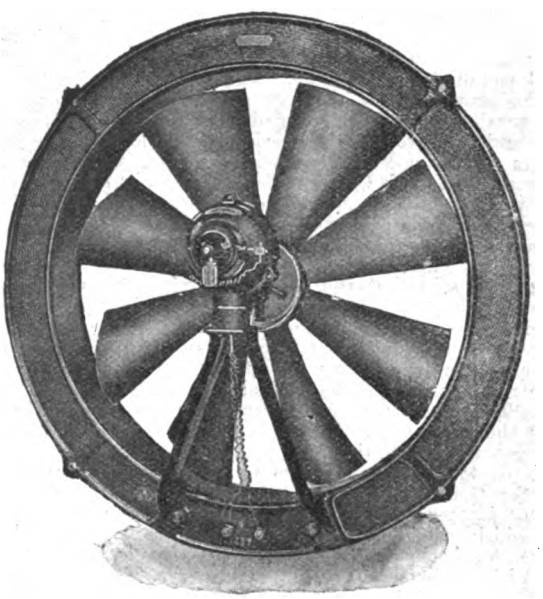

Fig. 2.—Fan with Friction Gear.

blades. As shown in the figure, the bearing of this ring is supported from the motor frame, with an ingenious spring arrangement to keep the wheel pressed on the ring. The gear ratio of the fan shown is 5 to 1. The high efficiency obtained is partly due to the large arc of contact of the two wheels, while the use of the gear enables a cheap high-speed motor to be employed to drive the fan at its most efficient speed; that is, to obtain a steady movement of the air without any churning.

An example of the vibratory generators which are used as a substitute for ringing machines in telephone installations is

Digitized by Google

also shown working. The instrument consists of a transformer with an open magnetic circuit, and an armature which vibrates to and fro before its laminated iron cores, and carrying a clapper rod. When the rod is in motion its contacts alternately cause the one and then the other of the two primary windings of the transformer to be connected to the D.C. source, so that rapid reversals of the magnetic flux in the cores are brought about, whereby alternating currents are induced in the secondary coil wound on the cores. The two halves of the A.C. wave produced are identical and approximately sinusoidal. No sparking ocurs, although no condensers are used, and the sparkless working is secured by proper adjustment. The frequency is altered by varying the air-gap between the cores and armature. When supplied from a 6-volt dry-cell battery, a normal type generator supplies 20 to 25 cycle current at a pressure of about 35 volts. Vibratory generators can be obtained for delivering 500 to 700 cycle current for signalling and telephone work and for very high pressures.

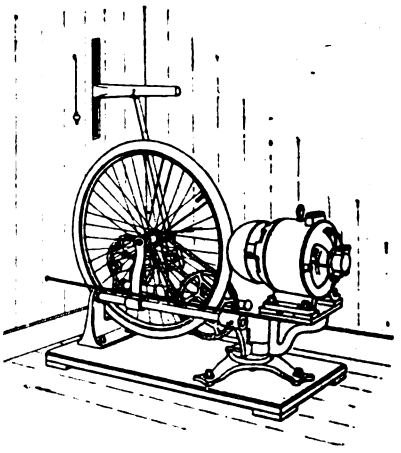
The show-rooms and offices are provided with a system of loud-speaking telephones. The instruments are fitted with vibratory generators for giving the call current, and the coils of the generators are used in place of the induction coils of ordinary instruments for the speaking current. In one pattern of instrument, it is not necessary to take off the receiver, but immediately after a call has rung, the message can be heard some considerable distance away from the instrument. This is already in use in some generating stations, and enables the engineer to hear and carry out instructions in spite of the noise and without going to the telephone. A number of trembler and single-stroke gas and water-tight bells for working off 100 volts or even 200 volts lighting circuits are also shown.

The Adnil Electric Co. are also arranging to supply the British market with heavy brass stampings produced by the large presses at the Bergmann Metal Works. We saw some splendid examples of this work, and it is stated that many stampings can be produced at less than half the cost of similar castings, including the cost of turning up and finishing the latter.

THE WELSBACH METAL FILAMENT LAMP: ACTION BY GENERAL ELECTRIC CO.

SUMMONSES WITHDRAWN.

When the hearing of the summonses by the General Electric Co., Ltd., against the Welsbach Incandescent Gas Light Co., Ltd., was resumed at the Clerkenwell Police Court on Saturday, it was announced that an agreement had been arrived at between the two parties. It will be remembered that the General Electric Co. had summoned the Welsbach Co. under the Merchandise Marks Act for applying a false trade description to the metal filament lamps which they had recently put upon the market. The lamps in question bore the words, "Welsbach Aur," and advertisements had been issued in which it was stated that Baron Von Welsbach was the inventor of the original metallic filament lamp. The combination of the words upon the lamp and the statements in the advertisement were, the General Electric Co. alleged, calculated to mislead the public, and to give the impression that the lamps were the invention of Baron Von Welsbach, and were manufactured by the German Welsbach Co., by whom the original metal filament lamps, viz., Osmium lamps, were manufactured. The General Electric Co. are the sole agents in this country for the German Welsbach Co.'s electrical goods.



Mr. Rufus Isaacs, K.C., M.P., on behalf of the General Electric Co., said that the case had arrived at a point when the parties felt that it became useless to continue the investigation, or to ask for a judgment from the magistrate. The defendants would admit that Baron Von Welsbach was not the inventor of the lamps they advertised, nor was the Welsbach Co. the manufacturer. It would also be stated on their behalf that the lamps were not manufactured by the German Welsbach Co. (or the Auer Co.). The defendants would also state that it was not their intention, in issuing the advertisements complained of, to mislead any persons in the manner complained of by the General Elecrtic Co., and they had agreed not to issue any further advertisements of such a character containing words which would be calculated to lead persons to believe that the Welsbach Co. manufactured the lamps, or that Baron Von Welsbach invented them. Upon such a statement being made, it appeared to him that the right course would be for the proceedings to be terminated by the withdrawal of the summonses.

Mr. A. J. Walter, K.C., said he agreed entirely with Mr. Isaacs' remarks, and desired to say on behalf of the Welsbach Co. that they had not the slightest intention, in issuing their advertisements, to lead persons to believe that the lamps were the invention of Baron Von Welsbach, or were made by the Welsbach Co. here, or the German Welsbach Co. He would go further, and say that it was not the intention to repeat the advertisements complained of, or to issue any advertisements which would be likely to have the effect referred to. Of course, the Welsbach Co. would continue to mark their lamps "Welsbach," and also to add "Aur," which was their trade-mark.

Mr. Bros, the magistrate, thought that the parties were very wise, especially in view of the fact that that inquiry was merely a preliminary skirmish for another inquiry in which the same proceedings would have to be gone through, and the same expense incurred. The summonses would, therefore, be withdrawn.

AN ORGAN-BLOWING EQUIPMENT

THE accompanying illustration shows an ingenious apparatus which has been introduced by the Kinetic Co., Ltd. (84 Leadenhall Street, London) for applying electric power to existing manually-operated organ-bellows. The apparatus is called the "Rotasphere," and comprises a small shunt-wound motor driving a crank-wheel attached to the bellows through an automatic variable-ratio friction gear. The motor is pivoted on a vertical spindle, and swings in a horizontal plane. On the end of the motor-shaft is a smooth hemisphere of aluminium which is in contact with the pneumatic tyre of an ordinary bicycle wheel, and thus constitutes a friction bevel-gear of variable ratio. The usual cycle-chain and sprocket-gear still further reduce the speed, and the final chain-wheel transmits reciprocating motion to the bellows-handle by means of a crank. Ball bearings are used throughout; and bearings, wheels, sprockets, chains, crank, &c., are made of standard cycle fittings.

ORGAN-BLOWING EQUIPMENT WITH VARIABLE RATIO FRICTION DRIVE.

Replacements, therefore, can be obtained everywhere. There is said to be no slip between the aluminium hemisphere and the tyre, and therefore practically no wear. The control is automatic, and is effected by swinging the motor, the speed of which remains constant. The swinging bracket is connected to the organ reservoir by a chain running over pulleys and adjusted to draw the motor round through an arc of 90° against the pull of a spring. The rising and falling of the reservoir thus causes the speed of the bellows handle to vary from zero to maximum, according to the demand of the organ. The apparatus is simple to fit up, and, it is stated, can be supplied from the lighting circuit, as a ½-h.p. motor is sufficient for a moderate-sized organ. The floor-space required is very small, and the machine is practically silent. We are informed that the Royal College of Organists, London, has adopted this apparatus for one of its organs.

Conversion of Thermometer Scales.—Mr. M. E. J. Gheury has called our attention to a simple rule for converting Fahrenheit temperatures in Centigrade and *vice versa*, which was advocated by Mr. F. K. Furguson in the *Monthly Weather Review*, 1907. The rule is based on the fact that the common point of the two scales is −40°, and reads as follows:—"To convert deg. Fahr. into deg. Cent., or reciprocally, add 40 to the temperature, multiply by ⅘ to get Fahr., or by ⅝ to get Cent., and subtract 40."

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the meeting of the Institution on Thursday:—*Member:* J. C. Wigham. *Associate Members:* W. Alderson, F. R. Bader, L. C. F. Bellamy, G. H. B. Bernard, P. N. Biswas, J. M. Brewis, J. F. Brown, P. Conway, J. A. Cork, C. W. Cox, F. G. Cresswell, H. G. Baker Cresswell, M.A., N. Denison, A. O. St. John Dixon, M. I. W. Ellis, E. Gomersall, C. E. D. Greenhalgh, P. E. Gregson, F. L. Henley, C. E. Hollier, A. Howell, J. C. Hyde, A. H. Laurence, S. N. Mandal, H. J. Miles, D. T. Neill, S. E. Packham, E. J. Page, J. S. Pitkeathly, G. Shearing, H. G. Stephens, G. D. Vickers, R. Waring. *Students:* H. L. Crosby, B. Dees, G. B. Dent, H. R. Fisher, W. G. Ford, J. Pendlebury, L. H. Peter, F. E. Robinson, D. R. Smith, M. O. Teague, A. C. Towers, R. O. Udall, C. G. Wells, W. V. Wright, F. V. Wythes.

Digitized by Google

HIGH TENSION TRANSMISSION

PROF. E. W. MARCHANT and Mr. E. A. Watson have sent in a written reply to the discussion on their Paper on "Recent Developments in the Transmission of Electrical Energy at High Tension on Overhead Lines," read before the Manchester Local Section of the Institution of Electrical Engineers, as there was not time for them to reply at length at the meeting. An abstract of the Paper and the discussion thereon was given on page 1049 of last week's ELECTRICAL ENGINEERING. In the Paper, the authors considered the principal features of high-tension transmission as carried out in modern plants in America, and in the discussion the applicability or otherwise of some of the methods described to this country was considered.

After commenting on some points Mr. Miller had raised regarding the hydraulic features, they remarked in reference to Mr. Peck's statements that electrolytic arresters were almost universal, and the common practice was to charge them every other day. With regard to telephone interference, complete neutralisation of induction was produced by transposing the transmission wires if the length of the line corresponded with a complete number of revolutions of any one wire of the line; if the telephone wire was transposed twice as often as the transmission line, the electro-magnetic induction was neutralised not only on the whole line, but on each section between two transposing towers. Prof. Schwarz's account of the latest results obtained for the dielectric strength of air was very interesting, and tended to confirm the belief that the dielectric strength of air in bulk was very much lower than 38 kilovolts per centimetre. The figures given in the Paper were derived from experiments made at the University of Liverpool on the brush discharge from a wire in a concentric tube. They were also confirmed by experiments made by Professor H. T. Ryan at Cornell University. Prof. Schwarz's account of his experiments on the behaviour of steam blown against a high-tension wire appeared to give a striking illustration of the way in which the ions were shot away from the charged wire. These ions would presumably act as neuclei on which the steam would condense and would thus be rendered visible.

Dr. Rosenburg stated that with large asynchronous generators it was not only necessary to bring them up to speed before switching in, but also to have them in phase. This surely was incorrect, for a squirrel-cage machine as they are cannot be said to have any "in-phase" position at all. The surge caused by throwing such a machine unexcited on to the circuit would probably not be any greater than if a transformer of the same size were suddenly switched on. They did not actually see any asynchronous machines acting as generators pure and simple, but they saw quite a number of the asynchronous exciter sets which are mentioned in a letter from Mr. Lea, of which the following is an extract:—

"We have quite a large number of these machines on our system; use them, in fact, in all of our large power-houses. These are not used as induction generators for their value as energy producers, but merely for the purpose of taking advantage of their characteristics for the purpose of governing the exciter water-wheels. About 1898 or 1899, in the installation of hydro-electric plants, a great deal of difficulty was experienced in obtaining a satisfactory water-wheel governor for the purpose of obtaining regulation to admit of parallel operation. A great many governors were tried, and eventually the Lombard governor and governors of similar character were adopted for the generators. However, they were at that time (the plants being small) considered too expensive for the exciter sets, which were then, as now, almost entirely water-wheel driven; being the successors to the belted exciter with its inherent difficulties; that is, when the generator tended to slow down, due to a sudden load coming on, the belted exciter slowed down also, with the result that at the time an increased field was needed, the field was actually weakened. This had led to the installation of water-wheel driven exciters. With the water-wheel driven exciter, however, the cost of a good governor seemed prohibitive, and the ordinary induction motor-driven exciter, due to poor speed regulation of the induction motors then commercially obtainable, was almost if not quite as bad as the belted unit, about the only difference being that there was no exciter belt to break. Another difficulty that was experienced in the high head plants particularly was that, owing to the smallness of the nozzle on the exciter wheel, it was very readily choked up by twigs and other small articles, with the result that it was not infrequent that the plants shut down from that cause. In the East, at Niagara, the difficulty of regulation was taken care of by placing an artificial load on in the form of a resistance in the shunt with the generator fields. The exciter wheel then was run at constant load, which was divided between the resistance and the generator fields, as conditions required. A constant load, however, was kept on the water-wheel at all times. Another plan considered out here by the late Mr. E. Theberath was the substitution of a battery for a resistance so that the exciter and its wheel was continuously operated at full load, and, in case of exciter water-wheel trouble, the generators were carried on the battery. The installation of batteries, however, was considered too expensive in small plants, and their subsequent maintenance and repair called for considerable labour and special materials, electrolyte, &c., which were not always available at the small power plants in the mountains. Theberath and myself, therefore, in order to do away with the induction motor, developed a scheme using a synchronous motor, water-wheel, and exciter coupled together on the one shaft, and operating the other water-wheel at full load at all times. The difficulty with this, however, was due to the fact that if for any reason there was trouble with the water-wheel, the synchronous motor fell out of step, and it would be difficult to start it again. A special design of synchronous motor was then gotten up that would have some of the self-starting characteristics of the induction motor, but the set was never built, since about this time Steinmetz's Paper on the induction generator was published, and Theberath immediately recognised that this machine had the characteristics of that we were looking for. A set was installed, and the results obtained were so good that they have been used ever since on this system, and, in fact, the Theberath exciter set will be found in use now on most systems in the West."

Mr. Pearce had referred to the question of capital costs. In most hydro-electric stations these were considerably higher than in steam-turbine stations. The cost of prime mover, dynamo, transformers, and switchgear would be rather greater for the steam plant than for hydraulic plant. In considering the relative capital costs, the expenditure on hydraulic works, the pipe-line, &c., must be set against the cost of boilers. In almost every case the hydraulic work is much more expensive, though it is conceivable that with particularly favourable conditions and large powers the hydraulic station might be the cheaper of the two. The cost per kw. of the new Winnipeg station will, it is estimated, be very little in excess of the cost of the most modern steam-turbine station. The cost of electrical energy per B.T.U. is usually higher in America than in England, though the charge for power purposes at Niagara was only £2 per h.p. year.

Underground systems are never met with outside the large towns, so that the extension of an underground cable system by an overhead line is a case which has not received any consideration.

Mr. Chamen referred to protection against lightning. The overhead earthed wire not only tended to protect the line from direct lightning stroke, but also screened it from the effects due to electrostatic induction. Lightning seems to cause much less trouble at 100,000 volts than on transmission lines working at 20,000 on 30,000 volts. There was considerable lack of confidence among station engineers in any form of lightning arrester as a protective against direct lightning stroke.

Mr. Fleming referred to the limit of pressure above which suspension insulators should be used. It was quite likely that it might be found good practice to have suspension-type insulators for lower voltages than that for which they have hitherto been employed. The suspension insulator is a comparatively new device, and it has therefore not been fitted on any of the 20,000 or 30,000 volt plants. Mr. Mallinson asked whether guard nets were required in America. They were only employed where a line crosses a very busy road, and were the exception rather than the rule. The requirement of guard nets in this country where a transmission line crosses a little-used footpath in a remote mountain district seemed a little overdone. In reply to Mr. Harlow, there were very few cases where the transformers were tied straight through. High-tension switching was the rule, and was absolutely necessary where duplicate lines are installed. The 110,000-volt plant of the Ontario Power Co. is not yet installed, although the plans have been prepared.

Royal Institution.—The following are among the Friday evening discourses which are to be given before Easter:—February 11th, "Electrical and other Properties of Sand," by Mr. C. E. S. Phillips; March 4th, "Magnetic Storms," by Dr. C. Chree, F.R.S.; March 11th, "The Ionisation of Gases and Chemical Change," by Dr. H. Brereton Baker, F.R.S.; and "The Dynamics of a Golf-ball," by Prof. Sir J. J. Thomson, F.R.S.

The New Manchester Exhibition Building.—We have received some further information regarding the large permanent exhibition building which is to be erected at Manchester. The building will be situated in Old Hall Lane, and will be 600 ft. long and 180 ft. wide, with a floor surface of 100,000 sq. ft. It will be electrically lighted throughout. Messrs. Davenport, Sons & Co. will commence work on the building contract next month. The following exhibitions have already been arranged for:—Manchester Industrial Exhibition, May 12th to June 25th, 1910; Textile Exhibition, October 8th to 29th; General Engineering and Allied Trades Exhibition, May, 1910, and June, 1911. The building has also been let for use as a skating rink from November 15th, 1910, to April 30th, 1911. Particulars of vacant dates can be obtained from Mr. W. Davenport, Ridler Place, Holland Street, Blackfriars, S.E.

PROSECUTION OF MINES MANAGERS

THE hearing of the case in which Mr. C. A. Carlow, General Manager, Mr. H. Rowan, District Manager of the Fife Coal Co., and Mr. W. E. Richardson, manager of the company's Foulford pit, were prosecuted for alleged infringement of the Special Rules with regard to electrical plant in mines, was resumed in the Dunfermline Sheriff's Court on Monday of last week before Sheriff Shennan. An account of the earlier part of the case was given on page xvii. of our supplement on ELECTRICAL ENGINEERING IN MINES of December 2nd.

Evidence was given by Mr. Richardson that prior to the visit of Mr. Masterton, there had been no criticism of the electrical plant by the Government inspectors. D. Sturroch, pit-bottomer, stated that he had never heard of anyone getting a shock from the lighting switch, and Messrs. A. B. Muirhead (of Messrs. Selby Bigge & Co.) and A. Anderson (of Messrs. Anderson & Boyes) expressed the opinion that the switch was not of a dangerous design. After other evidence had been heard, the Procurator Fiscal addressed the Bench for the prosecution, and was followed by Mr. Horne for the defence, who, in reviewing the evidence, claimed that the Crown had failed to sustain their case.

Judgment was given on Friday, in which the Sheriff dismissed the complaint against Mr. Carlow in respect that respondent was never appointed agent to the Foulford Pit, and that Mr. Rowan held an unrevoked appointment as agent of that pit. Messrs. Rowan and Richardson he found not guilty on the ground that the prosecution had failed to establish proof of the existence of the duty which they were said to have neglected. The Sheriff further expressed the view that the responsibility for supervision was too much divided up, and that the supervision of the practical mining work should be committed to skilled agents such as Mr. Rowan was universally known to be, while the commercial side was attended to by the management. Proceeding, he said "I have serious doubts whether H.M. Inspector's letter of January 30th, 1909, was a proper contribution under rule 55, section 11 (I.). These terms are too general. What meaning were the Fife Coal Company's officials to take from the words 'installed at your colliery,' when they have 41 shafts, some with electrical installations before 1905, some with new installations, and some without any electrical appliances?" As to H.M. Inspector's letter of May 3rd, the Sheriff holds that there is no presumption a letter reached Mr. Richardson. This letter led to the prosecution owing to the belief that its terms were being ignored. The Sheriff holds that the charge, in view of the evidence as to the switches and fuses, was not relevant. In regard to the fixed terminal boxes, he thought it would be hard to convict a manager of negligence who innocently misinterpreted a rule on the point. He agreed with the interpretation of the respondents that a fixed terminal box was a box containing fixed terminals and not a fixed box containing terminals. As regarded the cables, he could not hold the charge of negligence established. At the same time, he thought Mr. R. Nelson (H.M. Electrical Inspector of Mines) was right in impressing on agents and managers the urgent necessity of paying strict attention to the condition of the cables.

DISPUTE BETWEEN MESSRS. MUSGRAVE AND THE BRADFORD CORPORATION

ON Friday, December 3rd, in the Court of Appeal, before the Master of the Rolls and Lord Justices Moulton and Farwell, the appeal of Messrs. John Musgrave & Sons, Ltd., of Bolton, against a judgment of Mr. Justice Darling in June last, was dismissed with costs. The action was brought by Messrs. John Musgrave & Sons against the Bradford Corporation to recover £1,200, the balance of the price of a large slow-speed generating set. The tests were satisfactory, and 85 per cent. of the price was paid, but trouble was experienced during the guarantee period of 12 months, owing to the breaking of bolts at the coupling between the armature spider and the flywheel. The Corporation assumed the trouble to be due to deflection of the shaft, and put a new one in, for the cost of which (£1,996) they counter-claimed. The Judge found that as the Corporation engineer was not satisfied, the sum claimed by Messrs. Musgrave & Sons was not due; also that the latter were responsible for the expense of inserting new bolts, but not for the cost of the new shaft, as the old one was not proved to be defective. He therefore gave judgment for the Corporation on both claim and counterclaim, with damages £10. The Corporation also had the costs except on the issue on which they failed, namely, the alleged defective workmanship of the shaft. Full particulars were given in ELECTRICAL ENGINEERING, July 1st, 1909, page 601. In the course of the hearing of the appeal, Lord Justice Moulton expressed the opinion that it was Messrs. Musgraves' coupling that failed, but their counsel argued that, under the contract, they were not responsible for that. The failure was due, they said, to a defect in the dynamo armature flange, which was the fault of the Westinghouse Co. In delivering judgment, Lord Justice Moulton said that Messrs. Musgrave's claim could not be maintained as they had not got the engineer's certificate when the writ was sued. He also affirmed Mr. Justice Darling's judgment on the counterclaim, and dismissed the appeal with costs.

THE LEEDS FEED WATER CIRCULATOR

THE "Leeds Feed Circulator" has been designed with a view to improving the steaming capacity of all types of cylindrical boilers, but especially the Lancashire, the last 6 ft. or 8 ft. of which is generally admitted to be useless for steam-generating purposes. Near the centre of the boiler a sectional plate is affixed astride the furnace flues. The upper edge of this plate stands 3 in. or 4 in. above the working level of the water; the lower edge terminates half-way down the sides of the flues. From the lower point of this sectional division plate three horizontal plates 4 ft. long are carried, which run parallel to the flues, one on each side between the shell and the flue, a third one between the two furnaces. About 6 ft. from the rear of the boiler a second division plate is fixed, the lower edge reaching the underside of the flues, the upper edge 12 in. above the ordinary working level. The feed-water pipe is carried the full length of the boiler, and the water discharged into the space formed by the back division plate and the boiler; and as the back plate is higher than the working level, the water is compelled to gravitate and move along the underside of the flues towards the front end, assisted in doing so by the rapid evaporation taking place over the furnace flues. As rapid ebullition takes place over the furnaces, 50 per cent. or more of the heat generated in the furnaces is transformed to the water at this point. A proportion of the water is here rushed over the first division plate, and as there is not sufficient heat at this part of the flue to evaporate it, a portion gravitates and mixes with the incoming feed-water moving along the bottom of the boiler towards the furnace end. Thus the feed-water, from the time of entering the boiler, is being gradually increased in temperature, so that on reaching the front end of the furnace flues very little additional heat is required to turn it into steam. By feeding the boiler in the manner indicated, the foreign matter in the water will settle at the rear end of the boiler. The front end, where the work is done, will therefore be kept in better condition for steam raising. The appliance is the invention of Mr. W. H. Casmey, of the Yorkshire Boiler Co., Ltd. (Standard Buildings, Leeds), and it is claimed that by its assistance the evaporative duty of a 30-ft. Lancashire boiler is brought much nearer to that of a 24-ft. "Yorkshire" boiler.

The Design of Generating Stations.—At the Students' Meeting of the Institution of Civil Engineers, held on Friday, December 3rd, Mr. G. Ingram read a Paper on "The Design of Generating Stations." Having discussed at length the conditions influencing the choice of plant, the author went on to describe a suggested arrangement of plant for a shipyard, and for a large high-tension alternating-current station suitable for a bulk supply scheme, and concluded by showing a number of lantern-slides of various generating stations. An interesting discussion followed.

Northampton Institute Conversazione.—The annual conversazione of the Northampton Polytechnic Institute was held on Friday and Saturday last. Dr. Mullineux Walmsley, the principal, dealing with the progress of the Institute during the session 1908-9, stated that the equipment of the various workshops and laboratories had continued to develop, assisted by a further generous grant from the London County Council. In addition to the grant for ordinary developments, the Council had made a special grant of £5,600 for the equipment of a new generating station, which, in addition to providing the electrical energy required in the Institute for light and power, also gave the senior students opportunities of understanding the practical working of a modern generating station, and of making experiments on a commercial basis. The contracts for this station had been signed, and it was hoped that it would be in working order by Easter. For the fifth year in succession the whole of the second and third year engineering students were placed in commercial workshops during the summer period from Easter to Michaelmas, these workshops being spread all over the country, and in one case two students were sent as far afield as Genoa to take part in the erection of an important electricity generating station there. Sir John Wolfe Barry, K.C.B., F.R.S., prior to presenting the certificates and prizes to the successful students, gave an interesting account of the development of technical education in London, and of the part taken in this development by the great City Companies and the London County Council. The great City Companies had spent something like £800,000 upon technical education, and were now spending between £23,000 and £25,000 per annum. The Institute buildings, as usual, were thrown open to visitors on Friday and Saturday, work being in progress in most of the departments. On Saturday a series of entertainments were also given, and the attendance seems to get larger every year.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[*Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."*]

HOLOPHANE GLASSWARE.—A list from Messrs. Siemens Brothers Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston, N.E.), gives particulars of the latest designs of holophane globes and reflectors, which are particularly suitable for use with tantalum lamps. These well-known glasses are designed on strictly scientific principles, and secure an efficiency of illumination, diffused or concentrated, as desired, unattainable with ordinary shades, while unpleasant glare is effectually avoided. Some further particulars of these shades, &c., were given in ELECTRICAL ENGINEERING, November 25th, p. 1013.

AIR COMPRESSORS.—A catalogue of "Sentinel" air compressors is to hand from Messrs. Alley and MacLellan, Ltd. (Sentinel Works, Glasgow). A number of patterns of compound interlocking compressors for electrical and other methods of driving are included.

CHRISTMAS-TREE LIGHTING.—The British Westinghouse Electric & Manufacturing Co., Ltd., are sending out a seasonable little leaflet describing special complete outfits for Christmas-tree lighting, consisting of a set of eleven-volt candle lamps, with holders and clips, ready for connecting up any number in series to suit supply voltages.

WATER-TUBE BOILERS.—A catalogue and a leaflet from Messrs. Hawkesley, Wild & Co., of Sheffield, describe the "Suckling" water-tube boiler, which is claimed to be particularly suitable for electrical generating stations. The boiler is composed of one or more sections, each section is a complete unit in itself, and may be duplicated to any extent according to the heating surface required. It consists of two drums arranged one above the other, the upper or steam, being horizontal and the lower or water drum inclined. These two drums are coupled by means of a large tubular connection at each extremity. In the intervening space between the large connections are the smaller water tubes, which are arranged in vertical rows and expanded into the upper and lower drums. The upper drum is suspended from a steel framework and the bottom drum is supported on a cast-iron cradle mounted on brickwork; the boiler is therefore built on a flexible system, any portion being free to expand or contract without straining. The large connections act as supports, and so relieve the small tubes of all strains. All the tubes are slightly curved so that they enter the two drums radially, and also provide for expansion and contraction. They are all bent to the same radius, although the extent of the curve is less as the centre line of the drum is approached.

ELECTRIC POWER FOR WEAVING.—We have received from Messrs. Siemens Brothers a reprint from *The Electron* of an article describing the electric power installation, carried out by the Siemens-Schuckert-Werke at a weaving-shed in the jute mills of Messrs. W. Blütchen & Sons, Vetschau. Three-phase induction motors are used in conjunction with special slipping clutches and gear reduction.

INSULATING VARNISHES.—We have received from Mr. G. Braulik, 8 Lambeth Hill, Queen Victoria Street, particulars of a number of preparations in use in the electrical industry, produced by Messrs. B. Paege & Co., of Berlin, for which firm Mr. Braulik has been appointed agent. These include several acid-proof paints and varnishes, insulating varnishes, both for backing in the oven, and for drying quickly in the open air, and cable and joint-box compounds. A stock of all these preparations is kept in London.

ARC LAMPS.—Mr. Braulik also sends us a coloured leaflet illustrating a new design of flame arc lamp cover in green, relieved in bronze, with hexagonal type globe.

PEEBLES WORKS AND MANUFACTURES.—Messrs. Bruce, Peebles & Co. (Edinburgh) are issuing an interesting booklet containing an illustrated description of their works, and some notes on their principal manufactures. The Electrical Department was founded in 1897 at the firm's old Tay Works, Leith, and its rapid growth necessitated a move to the present factory in 1903. The whole establishment is on thoroughly modern lines, and the main shop alone is 600 ft. by 150 ft. Among the principal examples of the firm's products illustrated in the booklet are large and small induction motors, continuous current machinery, large alternators, both steam- and water-driven, turbo-alternators, traction motors, &c., and the well-known Peebles-La Cour motor converter.

METAL FILAMENT LAMP FITTINGS.—A new pamphlet from the Wardle Engineering Co., Ltd., 196 Deansgate, Manchester, describes the latest designs of the well-known "Streetlite" fittings for motor filament lamps. These fittings have several features to recommend them, including excellent provision for ventilation, and the larger sizes are principally intended for shop lighting and such purposes where enclosed arc lamps have hitherto been common. They vary in size from those for one 50-c.p. lamp to a 600-c.p. fitting, and forms for exterior, interior, shop window, and railway station lighting have been standardised.

IRON CASTINGS.—Messrs. Wilson, Pease & Co., of Middlesbrough (London agent, A. H. Sharpe, 8 Eastcheap, E.C.), are issuing a booklet calling attention to the large foundries where they specialise in the production of direct castings from the blast furnace without second melting, for railway, tramway, and other purposes. They have also a patent brake block with a steel back, upon which the body is cast, and a patent tramway anchor chair.

SIGNS AND CHRISTMAS TREE LIGHTING.—New leaflets from the Electrical & Engineering Supplies Co., Ltd. (36 and 37 Upper Thames Street), describe a very simple form of electric flashing sign in which a single lamp is used, and complete decorative lighting outfits for Christmas trees, &c.

THE O.S. WIRING SYSTEM.—The second part of their catalogue, relating to this system, has been issued by Messrs. Siemens Brothers & Co., Ltd. This deals with "Kalkos" conduits and fittings to be used in conjunction with the "Metacase" conductors described in the first part, to which we referred at some length in ELECTRICAL ENGINEERING, Oct. 28th, page 934. This combination is particularly recommended where a fully watertight system is required. Also where concentric wiring is permissible, the Kalkos system can be employed throughout or in combination with Stannos wires. The catalogue is very complete, and contains a large range of material, accessories, and apparatus for wiring on this well-known system.

ADVERTISING.—We have received a circular from J. Conway Price, advertising specialist, 151 Fleet Street, E.C., containing an offer to electrical firms to submit designs for advertisements, and giving some effective examples of his work.

Dinner of Siemens' Apparatus Department.—On Saturday, the 4th inst., the staff, foremen, and mechanics of Messrs. Siemens Brothers & Co.'s apparatus department, Woolwich Works, held a dinner at the Assembly Rooms, Old Charlton. The chair was taken by Mr. F. Hird, manager of the department. The toast of "The Firm" was proposed by Mr. Jones, foreman of the Railway Signalling Department, and responded to by Mr. F. Hird, the terms of both speeches showing the appreciation by the employees of the conditions of their service. Mr. Seaton, one of the oldest mechanics in the instrument shop, proposed the toast of "The Foremen," and Mr. Forrest, general forman of the Apparatus Department, replied in a witty speech which dealt with responsibilities. The visitors were toasted by Mr. Halliwell, and one of the best speeches of the evening was the response by Mr. G. H. Hume, who, now a barrister, entered the firm as a pupil in the Apparatus Department some twenty-five years ago. The most popular toast of the evening was that of "The Chairman," proposed in felicitous terms by Mr. Streeter.

Theft of Electrical Instruments.—Before the Common Sergeant at the Central Criminal Court, W. J. Victor Duncan, Louis Ernst, and Arthur Pamington were charged last week with stealing electric instruments, the property of the Foxcroft & Duncan Engineering Co., Ltd., and receiving them knowing them to be stolen. It was alleged by the Company that Duncan and Ernst had stolen six cell-testers and other articles from the company, some of which were found in the possession of Pamington, who kept a stall in Farringdon Road. The business had previously been carried on by Duncan, but had since been turned into a limited liability company. Duncan alleged that the goods were given to Ernst before the company came into existence, as commission for introducing the syndicate to form the company. Eventually all the defendants were discharged.

Seeing at a Distance.—It is reported that Dr. Ruhmer hopes to exhibit at the Brussels International Exhibition next year, a full-size apparatus for enabling objects to be seen at a distance. The experimental apparatus constructed by Dr. Ruhmer comprises a screen of selenium cells, on to which the object to be viewed is projected by a lense. The variation in resistance of the cells affects the transmitted currents, and these are caused to reproduce simultaneously the object on a screen at the receiving end. As yet simple patterns only have been reproduced as the number of cells is small. A full-size screen for reproducing portraits, &c., is stated to contain 10,000 selenium cells, but no details of the apparatus are yet available.

Metropolitan Association of Electric Tramways Managers.—The members of this Association held a meeting on Friday, the 10th inst., at the Municipal and County Club, Whitehall, S.W. Sir Clifton Robinson was unanimously elected chairman of the Association, and Mr. Goodyer was re-elected honorary secretary. Various matters relating to metropolitan tramway interests were discussed.

Distribution of Electric Power.—Mr. J. S. Peck read a Paper on Saturday last before the Manchester Association of Engineers on "Distribution and Application of Electric Power." He pointed out the advantages of three-phase and two-phase three-wire distribution and high voltages, and discussed some features of turbo-generators. In dealing with motors, he spoke of the wider speed variation rendered possible by the introduction of commutating poles, and considered also the field of usefulness of the single-phase commutator motor.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Pubiished Dec. 9th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

21,693/08. **Signalling System for Mine Haulage and Winding.** R. RUTHERFORD. This patent will be dealt with in the Mining Supplement to ELECTRICAL ENGINEERING of January 6th, 1910.

24,533/08. **Cheap Wiring System.** J. S. HIGHFIELD. The two insulated conductors are separated by a web of insulating material or tape, which is cut away at corners where the conductors are carried through a fitting of insulating material. The inner conductor is bent to take up the extra length. At joints, separate metal connectors are pressed into contact with the bared conductors by means of split sleeves. These are corrugated or otherwise caused to make a good and fast connection by the use of a special pair of pliers, covered by one claim of this patent. Various methods of forming the tape conductor and of fixing it are also described. Four claims, fourteen figures.

24,854/08. **Split-pole Converter.** BRITISH THOMSON-HOUSTON CO., LTD., and F. P. WHITAKER. The auxiliary poles of a split-pole converter have a series winding both for producing a commutating field and for changing the ratio between the A.-C. and D.-C. volts, to give a compounding or over-compounding effect at full load. The brushes are given a backward lead, thus allowing the auxiliary-pole flux to add to the main-pole flux at full load, but the lead is not sufficient to remove the coil under commutation from the influence of the auxiliary pole. Five claims, one figure.

27,212/08. **Ignition Commutator.** C. CECIL and H. P. BRONSDON. The commutator is caused to move longitudinally by a governor of the sliding-weight type, so that the time of contact is dependent upon the speed of the engine; the higher the speed, the earlier is the contact made. A construction of combined commutator and governor is described, in which the spring of the latter can be adjusted from the exterior. One claim, two figures.

9,275/09. **Starting Device for Electric Pulley Block.** THE ELECTRIC PULLEY BLOCK CO., LTD. (*A. C. Gese*). Besides the rubbing contacts on the rope wheel, there is a projecting lug; and the contacts are so arranged that whilst the wheel is in such a position that this lug is engaged by a spring stop, no current passes to the motor. On pulling the rope downwards the motor is started, and on releasing the rope, the wheel flies back under the influence of a spring until the lug comes into contact with the stop, and the motor stops. Other fixed contacts for reversing are arranged on the other side of the stop. The stop is raised to let the lug pass, by a stronger pull on the rope, which causes a sliding block (with a limited movement) working in the wheel groove, to force the stop up and allow the lug to pass to the other side. The lug is returned in the same way. Six claims, four figures.

14,091/09. **Electroplating.** LANGBEIN-PFANHAUSER-WERKE AKT.-GES. Apparatus for the uniform and rapid electroplating of flat sheets or rods, comprises rollers or cylindrical anodes covered with felt, or other porous material, and placed one above the other. The cylinders are slowly rotated, and the sheets or rods passed between them. A continuous flow of the electrolyte over the rollers is provided for, and current is carried to the roller surfaces through the shafts, and the sheets or rods pass through metal rollers connected to the negative terminals of the supply. A constant pressure of the rollers, and therefore a constant current-density is arranged for, and as the distance between the electrodes is only the thickness of the felt, *i.e.*, one or two millimetres, the pressure required for a high-current density is comparatively low. Two claims, one figure.

15,203/09. **Motor Controllers.** H. B. VAN DAALEN. In a combined starter and speed regulator for compound-wound traction or similar motors, two rheostats are successively actuated by means of a single arm. This arm is so mounted on a spindle and acts upon two other independent arms in such a manner that, on its backward movement, the other arms return successively and gradually to their former positions from any point in the forward movement. Six claims, seven figures.

16,537/09. **Motor Starters.** SIEMENS BROS. DYNAMO WORKS, LTD., and E. SCHUPP. In some patterns of motor starters, a metal contact piece is pivoted to the contact arm and makes contact successively with a series of carbon rollers in advance of the corresponding main contact pieces. The present invention covers a constructional improvement by which a large area of contact is obtained, as well as a quick movement from roller to roller. This enables heavy currents to pass through these contacts without glowing of the carbon or sparking. The metal contact piece pivoted on the end of the arm has a concave surface to engage with the carbon rollers, and moves round so as to sustain this contact except during the instant of movement from one roller to the next. Three claims, two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke-Ges.*), 14,505/09; GEBR. SIEMENS & Co. [Manufacture of electrodes] 23,171/09.

Dynamos, Motors, and Transformers: SCHARF [Regulation of D.-C. motors] 24,794/08; TAYLOR [Machines] 16/09.

Electric Ignition: MILTON [Magneto-ignition] 22,271/08.

Electrometallurgy and Electrochemistry: BOULT (*Newell Manufacturing Co.*) [Metallising non-metallic articles] 5,675/09; PATTERSON and HOPPER [Dry cells] 11,155/09.

Incandescent Lamps: FULLER [Manufacture of refractory conductors] 17,619/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Treatment of filaments] 2,389/09; HOPFELT [Lamp manufacture] 8,146/09.

Storage Batteries: MARINO [Treated wood for separators, &c.] 2,641/09, and [Batteries] 2,683/09; MARSEILLE and GOUIN [Preventing dropping of active material] 15,373/09.

Switchgear, Fuses, and Fittings: MCLEAN [Lamp-support] 875/09; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Lightning arresters] 2,529/09.

Telephony and Telegraphy: VON LEPEL [Oscillation generator] 17,349/08; FESSENDEN [Wireless signalling] 25,305/08; THOMPSON (*Ges. für Drahtlose Telegraphie*) [Oscillation generator] 6,424/09.

Traction: SAMAIA [Control of points] 25,314/08; HADFIELD and BROWN [Operating points] 25,436/08, and 12,321/09; JOHNSON [Operating points] 27,554/08; MUNRO and RAILLESS ELECTRIC TRACTION Co. [Trolley heads, &c.] 1,067–77/09.

Miscellaneous: ARON [Lamps for vehicles] 25,389/08; CROWDEN [Illuminated signs] 25,403/08; CHILDS and HILL [Lift control] 1,086/09; JULIUS SAX & Co. and WHEAT [Indicators] 1,985/09; RAUSH [Time-alarm device] 12,195/09; SAHMER [Door locking and unlocking device] 15,991/09; BROCKWAY and PHILLIPS [Ventilating fans] 16,043/09; HARRISON (*Baker*) [Influence machine] 21,529/09; GREENBAUM [Synchronous running of kinematographs and phonographs] 21,675/09; COLLIER [Burglar alarm] 24,453/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Arc Lamps: KÖRTING & MATHIESEN AKT.-GES., 26,706/09.

Dynamos, &c.: FORTESCUE [Transformers] 23,938/09.

Telephony: SIEMENS & HALSKE AKT.-GES. (Automatic telephone exchanges] 21,978/09.

Miscellaneous: MASCHINENFABRIK OERLIKON [Electro-hydraulic press] 24,784/09; KORBER [Resistances] 26,929/09.

Amended Specification Published

The following amended Specification can now be obtained.

19,886/08. **Induction Coil.** H. F. BIGGE and F. R. BUTT. A disclaiming note was added to this specification. See ELECTRICAL ENGINEERING, December 2nd, 1909, page 1,030.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

24,577 of December 23rd, 1895. **Supporting Flexible Conductors.** T. LAURIE. Flexible conductors are attached at intervals to runners which slide along horizontal wires or rods, in order that the conductors shall not hang down if the lamp or other apparatus at its end is moved to one side.

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: E. A. CAROLAN (*General Electric Co., U.S.A.*) [Mercury vapour lamps] 18,343/03, and 18,173/04; E. R. GROTE and M. V. ELY, 17,106-7/05.

Dynamos, &c.: BRITISH THOMSON-HOUSTON Co. (*A. D. Lunt, U.S.A.*) [Obtaining neutral connection of armatures] 17,025/01; BRITISH THOMSON-HOUSTON Co. (*W. S. Moody*) [Transformer windings] 18,818/02; E. A. CAROLAN (*General Electric Co., U.S.A.*) [Insulation of edge-wound strip field coils] 18,251/03; M. LATOUR [Repulsion motor] 18,105/04; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Resistances for armatures] 18,361/04; W. ARMISTEAD (Cooling commutators] 16,971/05.

Electrometallurgy and Electrochemistry: J. HARRIS [Air ozoniser] 18,144/04.

Switchgear, &c.: C. G. GARRARD [Time-element relays for circuit-breakers] 18,199/04; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Traction controllers] 18,202/04.

Traction: A. J. BOULT (*F. H. Daniels*) [Rail bonds] 17,997/99.

Miscellaneous: J. L. MITCHELL [Coal-cutter] 14,958/00; L. OBRY [Gyroscopic ordnance firing-device] 14,989-90/00.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

The Council of the Institution of Electrical Engineers are inviting evidence on electricity in mines to be submitted to the Home Office. (Page 1072.)

We have received letters from a number of tramway managers on the relative merits of the trolley and bow forms of overhead contact for tramcars. Several speak strongly in favour of the bow contact, and some go so far as to say that if they were laying down their lines afresh they would unhesitatingly adopt the bow collector. (Page 1073.)

We have received two letters relating to the decision in the recent case between the Welsbach Co. and the General Electric Co. (Page 1074.)

Statements have been made that the disastrous fire which occurred in Clapham (London) on Monday was caused by electricity, but these should not be definitely accepted until further evidence is forthcoming. (Page 1074.)

The way in which the metal filament problem has been dealt with successfully at Harrogate was described in a Paper by Mr. G. Wilkinson (Borough Electrical Engineer, Harrogate) and Mr. R. McCourt, read recently before the Leeds Local Section of the Institution of Electrical Engineers. (Page 1075.)

The annual dinner of the Newcastle Local Section of the Institution of Electrical Engineers was held on Wednesday, December 15th. (Page 1076.)

An interesting Paper on "Continuous-current Boosters and Balancers" was read by Mr. W. H. Ker, on Tuesday of last week, in which he described several systems of two- and three-wire boosting and discussed the relative merits of each. (Page 1077.)

Two Papers dealing with the measurement of the overall efficiency of wireless telegraph plants were read before the Institution of Electrical Engineers on Thursday last. The first, by Prof. J. A. Fleming, contained a mass of information relating to special instruments and methods for high-frequency measurements, including a description of a differential thermometer for measuring the resistance of conductors to oscillatory currents, thermo-electric ammeters, and standard inductances and capacities. The Paper concluded with a detailed synthesis of the losses in the various circuits of the University College wireless plant, from which it was concluded that 78 watts were radiated in the form of electromagnetic waves, giving an efficiency from the transformer input of 10 per cent. Some

Digitized by Google

figures indicating the extremely low efficiency of transmission were also given. The second Paper, by Dr. W. H. Eccles and Mr. A. J. Makower, gave some efficiencies determined by dissipating the oscillations induced in the antenna circuit in a resistance enclosed in a calorimeter. A short-spark discharger of the Lepel type was used, and overall efficiencies varying between 4·5 and 14·4 per cent. were obtained. In the ensuing discussion Mr. Taylor, of the G.P.O., doubted whether Prof. Fleming had included all the losses in his synthesis, notably those at the earth connection. Prof. E. Wilson suggested that the granting of P.O. licences should be based upon the power radiated into the ether, and not the power of the generating plant. (Page 1079.)

AT the inaugural general meeting of the new Institution of Mining Electrical Engineers, held on Friday last at Manchester, the President, Mr. W. Maurice, delivered an address dealing chiefly with the position of the electrical engineer at a colliery, and the urgent need for placing the responsibility for the maintenance of the electrical plant in his hands. Further, Mr. Maurice emphasised the importance of careful attention to plant, illustrating his remarks from statistics. At the dinner held subsequently, Dr. Thornton expressed the opinion that A.-C. working would supersede D.-C. working in mines, and that even single-phase plant would eventually be used. Mr. Maurice, on the other hand, differed from Dr. Thornton on this point. (Page 1081.)

THE Comptroller-General has granted a patent to Messrs. Willoughby S. Smith and W. P. Granville for a flexible loading coil which can be inserted into a telegraph or telephone cable under the sheath in the course of construction, in spite of the opposition of Messrs. Siemens Bros. and Co., on the ground of anticipation by their 1906 patent. In both cases the coils are wound parallel to the length of the cable over an annular iron core. In the case of the Smith and Granville patent this core is a layer of iron wires wound transversely to the cable, while in the Siemens patent it is described as an iron cylinder, and rubber distance pieces are inserted between adjacent coils to give the whole flexibility. (Page 1082.)

MESSRS. LEPINE AND STELLING'S Paper on the German electrical industry, which led to a heated discussion on the general policy of the Institution at a recent London meeting, was further discussed last week by the Manchester Local Section of the Institution. A number of speakers took part, some of whom considered that the authors had generalised unduly from the practice of a few firms. (Page 1083.)

WE publish a letter from Mr. E. Garcke to the Secretary of the Institution of Electrical Engineers regarding the duties of the Institution. (Page 1084.)

A TUMBLER switch which also acts as an automatic circuit-breaker is described on page 1085.

ON Wednesday of last week a series of three explosions of gas occurred in cable boxes and manholes at the Blackfriars end of Queen Victoria Street. The gas had escaped from a bad leak in a pipe under the road and had collected in the boxes and manholes. As yet, the cause of the separate ignitions is unknown. No cables were damaged, but five men were injured and the traffic seriously interfered with. (Page 1085.)

AMONG the specifications published by the Patent Office on Thursday last was that covering the Lepel spark-gap for wireless telegraphy.—A simple method of attaching brush-holder spindles to rocker arms, covered by J. Taylor, of Mather & Platt, Ltd., consists in expanding a tubular spindle into a hole in the rocker arm or shrinking a socket on the arm round a solid spindle.—Apparatus for treating metal filaments is patented by the British Thomson-Houston Co.—R. Hopfelt describes a treatment for removing hydrocarbons from carbon and metal filaments consisting in glowing them in a gaseous halogen compound.—Special carbons for flame arc lamps of the converging carbon stop pattern are described by Siemens Bros. Dynamo Works; these have a longitudinal slot filled with a compound which crumbles away and allows the carbons to feed.—A patent has been granted to the Centralstelle für Wissenschaftlich-Technische Untersuchungen Ges. for an arc furnace, in spite of opposition.—Among the expiring 1895 patents is one by the Westinghouse Brake Co. for a railway signalling and point-shifting system. (Page 1086.)

A CORRESPONDENT comments on the interconnection and relations between the various engineering societies, and suggests that an advisory board should be formed to approach the founders of new societies with a view of preventing clashing of interests. Reference is also made to the new "Institution of Mining Electrical Engineers," the suitability of the name of which has been questioned. (Page 1087.)

AN electricity scheme has been prepared for Bishops Stortford.—It is estimated that £6,604 must be set aside annually until 1917 to provide the cost of renewal of the Cardiff tramway track.—Hastings Corporation have agreed with the Electrical Contractors' Association to carry their proposed wiring powers out through a contractor.—The L.C.C. have decided to charge £25,265 expenditure upon the G.B. surface-contact system against the General Reserve Fund.—St. Pancras Borough Council have been warned against transferring all their electricity profits to relief of rates, in view of the long period still unexpired of many loans.—Swindon Corporation have adopted a hire purchase wiring system.—Woolwich Council have refused West Ham Corporation permission to supply electricity in North Woolwich. (Page 1087.)

MARYLEBONE BOROUGH COUNCIL propose co-operation with manufacturers of ice-making plant in connection with a scheme of cheap supply. A sum of £3,000 is to be spent upon mains at Dundee; a high-tension three-phase switchboard is required at Erith; loans of £4,500 and £2,120 are to be applied for by the Battersea and Bermondsey Councils; a further loan of £1,000 is proposed by the Rhyl Corporation; a loan of £2,191 has been sanctioned to the Surbiton Council; 50,000 metal filament lamps are required by the Italian State Railways Department; and an expenditure of £1,312 is proposed upon mains at Torquay. (Page 1088.)

Use of Electricity in Mines.—The Council of the Institution of Electrical Engineers are considering the evidence to be submitted to the Home Office in connection with the inquiry on the use of electricity in mines. The Secretary of the Institution will be glad to receive in writing on or before January 10th next any observations which members may wish to make on the Special Rules of the Home Office for the Installation and Use of Electricity (Coal Mines Regulation Act, 1887) now in force.

Underground Telegraphs.—At a meeting of the Newcastle and Gateshead Chamber of Commerce on Friday, the Secretary reported a communication from the Postmaster-General stating that the underground telegraph line between Glasgow and Edinburgh had been completed with the exception of a short section within the city of Edinburgh. The line running southwards from Newcastle had reached Stockton, and the line to the west of England had reached Penzance. Extensions from Birmingham and Bristol had reached Worcester and Berkley. Communication by underground telegraphs was also to be established between Stockton and Leeds, where it would join up with the underground line from London. A second underground line is in progress between London and Birmingham, and a further extension of the line from London to Chatham would carry this on to Canterbury, the intention being to provide underground connections with the landing-places of the principal submarine cables between England and the Continent.

BOW COLLECTORS FOR TRAMCARS

WE have received several letters from tramway managers in this country on the controversy between bow and trolley collectors for tramcars, dealt with in an article in ELECTRICAL ENGINEERING, December 9th (page 1035). Some of the writers, in view of not having had any experience themselves with the bow collector, express some diffidence in giving a definite opinion upon its utility, but the following letters and extracts will be of interest as showing the way in which the matter is regarded:—

One of those most strongly in favour of the bow contact is Mr. A. A. Watkins (Manager and Engineer, Musselburgh and District Electric Lighting and Traction Co.), whose letter we give in full below:—

I have read the article on Bow Collectors for Tramcars in your issue dated the 9th inst. with much interest. From actual experience with bow collectors on tramcars I am convinced that they are in every way preferable to trolley wheels and booms, and would recommend the use of them on any line where the overhead equipment permits, *i.e.*, where no side reach is required. Bows save wear on trolley wire all over the route, but especially at the "running on" end of all ears, and, further, the ears and hangers do not have to sustain the blows which occur as trolley wheels pass under. All frogs and crossings are avoided, and there is no fear of danger to the overhead equipment through a trolley wheel leaving the wire. Bow strip renewals are cheaper than renewals to trolley heads, wheels, and bushes, and running is much quieter with bows. The only drawbacks appear to be the necessity for having the trolley wire over both up and down tracks, and in the case of single line, if the wires are run close together, one wire cannot be made dead, because the bows would bridge across the two wires.

Mr. H. Collings Bishop (Borough Electrical Engineer and Tramways Manager, Newport, Mon.), writes as follows:—

In my opinion the bow collector is one that should receive greater consideration than it has had in the past in this country, and were I putting down a new system of tramways I should be very tempted to consider its adoption seriously. There is no doubt that a large number of failures of supply and accidents more or less serious are caused by the type of trolley head in use in this country. The main difficulty, in my opinion, in adopting the bow collector on existing tramways is the extensive alterations that I think would be required to most. For instance, on bracket-arm construction there would be great difficulty in spreading the trolley wires sufficiently far apart to permit the collectors to pass each other. Then, again, assuming it was a single line, and that the trolley wires are already separated at passing places, one has to consider the possibility of an earth occurring on one trolley wire, which would prevent the use of the other trolley wire pending repairs, as when trolley wires run close together the bow would make contact with both. There is not the same difficulty on span-wire construction, but there is no doubt, at junctions, &c., considerable alterations would be required. It is, however, an interesting subject, and I hope correspondence will put points forward that will be of service to tramway managers generally.

Another tramway manager who strongly favours the bow contact is Mr. G. W. Holford (General Manager, Salford Corporation Tramways), who has written us the following letter:—

On the subject of the bow collector *v.* the trolley wheel I am bound to say that I believe that the introduction of the former arrangement would be of benefit to many tramway undertakings, and if we were a self-contained undertaking I would not hesitate in experimenting with the use of it on an extensive scale; but, fortunately or unfortunately, we are linked up with several other towns, and our cars have to travel under each other's overhead line. Before we could use the bow system it would be necessary to remove the many frogs and crossings at the junctions, &c., which would be a somewhat difficult matter in view of the several interests concerned. There would be, I feel sure, by its adoption a simplification in the overhead line construction, with consequent less cost and greater economy in the maintenance, and in many cases the employment of trolley boys might be dispensed with, as their chief duty is to guard the trolley rope. Again, I should think the cases of "trolleys leaving the wire" would be reduced to a minimum with the use of the bow, and even if they did the possible damage to the overhead equipment would be very much lessened. I trust that before long we may have an opportunity of obtaining the practical experience of the use of the bow system on some of our British tramway systems.

Mr. J. S. D. Moffet (General Manager, Rochdale Corporation Tramways), regards the bow with much favour, and writes:—

I am quite satisfied, and have been for some considerable time, that the bow collector would have been much more suitable, in every way, for this district, than the trolley wheel collector; and were it not for the expensive alterations its adoption would entail to our overhead equipment, we should have substituted it for the trolley a year or two ago.

Mr. L. Slattery (General Manager, Oldham Corporation Tramways) does not express himself so strongly, but writes:—

I consider, notwithstanding that they may have a tendency to shorten the life of trolley wires, and are somewhat more unsightly than the ordinary trolley booms to which we have all become accustomed, that if the aerial suspensions were specially constructed originally for this type of collector, it may be possible to obtain a higher degree of efficiency with a minimum of risk to the public (both passengers and pedestrians) without little (if any) additional maintenance costs to the undertaking.

A tramway manager who does not wish his name to be published, writes:—

I certainly do not see why we should not in England adopt the bow collector more extensively. It seems to me it is better, and likely to be less trouble in every way, than a trolley, and I understand the wear is not excessive with a modern type of bow.

Another well-known tramway manager and engineer writes that he has

A very favourable opinion indeed of the bow collector.

It will be remembered that the subject was referred to at some length by Mr. A. R. Fearnley (General Manager, Sheffield Corporation Tramways), in a Paper entitled, "Some Comparisons of Continental and British Methods of Operating Tramways," some extracts from which are given below:—

In 1907 I had the opportunity of experimenting with a bow collector, and while our overhead line had not been constructed for a collector of this type, we found that there would have been little difficulty in obtaining very satisfactory results with this arrangement if the overhead line had been suitable. Knowing the serious disadvantages of the trolley, and from what I have seen of the bow collector, I am inclined to the opinion that, as used on the Continent, it is the better arrangement. The trolley boom, with its attendant overhead fittings, is the most unmechanical feature of the whole of our tramway equipment. Many officials may state that their trolleys work with very little trouble, with few accidents, and at a low cost, but we must admit that, notwithstanding every precaution, many serious accidents are narrowly averted. The bow collector seems to give entire freedom from danger in this respect. It further very considerably simplifies the overhead fittings and construction work, although, on the other hand, it may shorten the life of the trolley wire. The cost of trolley upkeep in Sheffield for our last financial year amounted to £1,031 14s., or 0·0336d. per car mile. The cost on a line where the bow collector is in use was given to me as being 0·041d. per car mile, and, in my opinion, the bow collector would be a considerable advantage if it could be worked with such a small difference in cost.

Mr. E. Carden (General Manager, Dover Corporation Tramways), writes as follows:—

In reference to the very interesting discussion which has arisen as to the respective merits of each of these useful, if unsightly, pieces of equipment, after twelve years' highly satisfactory experience of the "swivelling trolley" with side bracket suspension, and no knowledge of the "bow collector," I can but favour the continuance of the "trolley" until some greatly improved method of power distribution and collection holds the field.

Among tramway managers who have expressed their views in favour of the trolley is Mr. C. W. Hill (General Manager, Bournemouth Tramways), who writes:—

I consider the trolley is more suitable for the majority of systems in this country.

Mr. H. Mozley (General Manager, Burnley Corporation Tramways), writes:—

This is a matter which has not been considered here, but from observations of others' experience (especially on the Laxey lines), we believe that the wear on the overhead wire would make the bow trolley prohibitive. We have not sufficient trouble with the trolley wheel to cause us to give the matter serious consideration. We have had gauge 000 wire in service since December, 1901, with a service varying from 2½ to 10 minutes. I question whether we should have had this wire in service now with a bow trolley.

THE CLAPHAM FIRE

MOST of our readers will have already read in the daily papers of the serious fire which occurred in a large retail drapers on Monday at Clapham (London). The first reports stated definitely that the cause of the disaster was the breakage of an electric lamp in the shop window, and the consequent ignition of cotton-wool decorations, celluloid combs, lace trimmings, and other flimsy, inflammable articles with which the window was trimmed. We would ask our readers, however, not to accept this version as correct until the conclusion of the inquest, when doubtless further evidence as to the origin of the fire will be forthcoming. The official report of the Fire Brigade says that the cause of the fire was unknown, and it appears that both gas and electricity were used for lighting the building. In some of the circumstantial accounts published—which, however, have not been confirmed—it is stated that a young shop assistant was removing something from the window, and in doing so knocked an umbrella against an electric lamp, which then set fire to the cotton-wool, &c., in the window. Obviously if the window was so arranged that a lamp could come in contact with the very inflammable material near it, it would be possible that the outbreak could be accounted for in this manner. On the other hand, it must not be forgotten that if the circuit was protected by a fuse, which doubtless it would have been in the ordinary course, the lamp would only have sparked for a very short time, possibly for only a fraction of a second, after the globe was broken, and even if the impact with the umbrella swung the lamp against the inflammable material, the chances of the latter being ignited were therefore only fractional. We repeat that, although it is conceivable that the fire may have originated through such a cause, the statement should not be accepted until further evidence is forthcoming.

Crystal Palace School of Engineering.—Mr. W. M. Mordey on Friday distributed the prizes to the successful students of the Crystal Palace School of Engineering.

The Brennan Mono-rail Patents.—Mr. Brennan has informed a representative of the *Times* that Herr Scherl has purchased an exclusive licence to work all the Brennan patents in Germany on payment of a substantial sum and a royalty upon all profits made in the undertaking. This licence also carries the right to export to German colonies. Herr Scherl has also acquired a licence to exhibit his car in the United States for a period of about three months, with an option to prolong the period for the full term of the original Brennan patent should he decide to do so at the end of the time mentioned. This is not an exclusive licence, and does not apply to the more recent Brennan patents. It is also stated that in 1905 the War Office agreed to give Mr. Brennan certain subsidies and facilities on condition that he should grant them a licence to use the system for military and naval purposes only, at a small royalty on the cost of the rolling stock required. In 1907 a licence was granted to the Indian Government by which they acquired the right to use the invention on all Government lines in India on similar terms. In 1908 the Kashmir Durbar acquired a licence to use the invention throughout their State on payment of a similar royalty.

Telegraph Traffic and Movements of Cable Ships.—After the repair of the cable between Puerto Plata and Martinique, the French cable steamer *Pouyer Querier* proceeded to repair the Cape Haiti-Mole St. Nicholas cable, which was effected on the 16th inst. She will next proceed to the Guianas, where one of the sections of the company's cable system has again given out. In the meantime messages for Dutch Guiana can be forwarded via the North Atlantic cable, and those for French Guiana via South America.—The Bathurst-Bolama cable is down, and telegrams for Bissao and Bolama can only be accepted at sender's risk. On the 14th inst. communication between Mozambique and Majunga was again working, and on the 17th inst. the Indo-European Telegraph Co. repaired the connection between Emden and Berlin. On the same day the Bagdad-Bassorah line was *hors de combat*, and on the following day the Medan-Kotaradja connection failed; telegrams for the latter place and Sabang have to be sent from Pang Kalanbrandan by telephone, or by post from Padang, Medan, or Penang. The Western Union Telegraph Co. has not yet succeeded in repairing its Atlantic cables. News of the repair of the Assab-Perim cable has not yet been received, although the line has been down since July 8th last. The Dakar-Covakry cable, down since August 19th last, remains so, as well as the Réunion-Mauritius cable. The Nicaraguan land lines are down, and code and cipher is prohibited in messages to Roumania. Martial law, proclaimed by the Government of Paraguay, has been ruling since June 19th last, and messages can only be accepted at sender's risk.

THE WELSBACH INCANDESCENT LAMP

To the Editor of ELECTRICAL ENGINEERING.

SIR,—We would like you to notice in your paper the result of our case with the Welsbach Co.

We felt compelled to start these proceedings because of an advertisement appearing in the daily Press which created the impression in the trade that the metal filament lamp which the Welsbach Co. offered was either a lamp manufactured by Auer Von Welsbach or by his process, or by one of the Auer Companies.

You will notice that counsel for the Welsbach Co. last week freely admitted that their lamp had no connection with either Welsbach or the Auer Companies, and cannot therefore in any way be considered to be an Osram lamp or a lamp made under the Osram patents or processes. By this we have attained our object, and have withdrawn the proceedings.

Yours faithfully,
THE GENERAL ELECTRIC CO., LTD.

71, Queen Victoria Street, E.C.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—*G.E.C.* v. *Welsbach*:—The attention of our clients, the Welsbach Incandescent Gaslight Co., Ltd., of 344-345 Gray's Inn Road, has been drawn to your report of this case, which is calculated to convey an erroneous impression which we must ask you to correct in your next issue.

What counsel for the company stated when the prosecutors, the G.E.C., intimated that they wished to withdraw the prosecution, was that it was never their intention to lead anyone to believe that their electric lamp was the invention of Dr. Auer von Welsbach, or that it was made by the Auer Gesellschaft; that whilst they would not repeat the former advertisement complained of, they would continue to mark their lamps "Welsbach," their own name, and their trade-mark, "Aur," would be continued upon their lamps.

In your report of the case, instead of referring to the Deutsche Gasgluhlicht Aktiengesellschaft as the Auer Company, as was done for convenience throughout the proceedings, you have referred to them as the German Welsbach Company, as if they were a distinct corporation, and this, coupled with the fact that you have also in the same paragraph referred to our clients as the Welsbach Company, makes it essential that publicity should be given to the above statement, so that the actual position and the exact statement made at the police court may be properly appreciated and understood.

Yours faithfully,
MICHAEL ABRAHAMS, SONS & Co.

5 Tokenhouse Yard, Lothbury, E.C.
December 21st, 1909.

Theft of Admiralty Wireless Apparatus.—At Portsmouth, on Tuesday, R. S. Knowlden, a dockyard draughtsman, was charged with stealing a wireless telegraph receiver from H.M.S. *Vernon*. It was stated that in all probability a very grave charge would be preferred against the prisoner, and a remand for a week was ordered.

Wireless Telegraph Notes.—It is stated that the German Minister for the Colonies has been conducting negotiations with the Telefunken Company for the purpose of establishing wireless telegraphic communication between Germany and her colonies. The height of the wireless telegraphy tower at Nauen, near Berlin, will be increased by about 160 ft., so that its radius of communication will be enlarged, and German colonies are to be equipped with wireless telegraph stations. Two stations have been erected at Angaur and Jap, in the German South Sea Islands. The distance between these stations is approximately 300 miles.

The Lepel Wireless Telegraph Co. established communication between Brunswick (Germany) and London last week.

A wireless telegraph installation has been installed at Folkestone Harbour for use in connection with the Channel steamer service.

Capt. Muirhead Collins, the Australian Commonwealth agent in London, has been instructed to secure a report from Mr. Charles Bright upon the Balsillie wireless telegraph system. The owners of this system are the Radio-Telegraph Co.

The Russian Government propose to establish a wireless telegraph station at Kamchatka, and has sent an official to the United States to make arrangements for the establishment of communication with Alaska.

The Trinidad Government have passed a law prohibiting ships from using wireless telegraph apparatus in the territorial waters of the colony.

Arrangements have been concluded with the Nederland Steamship Company for the equipment of the steamships *Grotius*, *Konig Willem II.*, *Oranje*, *Rembrandt*, *Vondel*, *Konig Willem III.*, and *Prinses Juliana* with the Marconi system of wireless telegraphy.

METAL FILAMENT LAMPS AND ELECTRICITY SUPPLY

A PAPER on the possible beneficial effects of metal filament lamps on supply undertakings, by Mr. G. Wilkinson (Borough Electrical Engineer, Harrogate) and Mr. R. McCourt, was read before the Leeds Local Section of the Institution of Electrical Engineers on Wednesday, December 15th.

The Paper was intended to give some idea of what has been done in Harrogate to counteract the effect which the introduction of metallic filament lamps has produced in a system where the bulk of the demand on the station is for lighting purposes, and where the supply is alternating current, conditions which admittedly favoured the largest possible use of the new lamps in the shortest possible time. With regard to the question as to whether the price per unit ought to be increased, it was felt that consumers are naturally chary of introducing new lamps, and that it was better not to recommend an increase in the price, but rather to adopt a policy which would educate the public to appreciate the possibilities of the new lamps.

In the case of street lighting, a 17-ampere open-type alternating-current arc lamp was displaced by way of experiment by a four-arm fitting having four 100-c.p. metal filament lamps. The public, without knowing anything of the saving in current, expressed themselves in no uncertain voice as being in favour of the incandescent lamps, largely because of the absence of the flickering and light variation. When it was further pointed out that not only was there a large saving in current consumed, but that the additional costs of arc lighting—viz., carbons, trimming, repairs, &c., were not necessary in the case of the metal lamps—instructions were given to convert the greater part of the arc lighting of the town to the newer form of illuminant. It was decided to deal first with a stretch of roadway in a residential district, then lighted by twenty open-type series alternating-current arc lamps, arranged in two circuits and supplied from two floating coil constant-current transformers, and it was arranged that eighteen of these arc lamp-posts should be fitted each with two-arm fittings carrying two 100-c.p. 200-volt metal filament lamps, and the remaining two posts fitted with four-arm fittings carrying four 100-c.p. 200-volt metal filament lamps. The 100-c.p. lamps are not enclosed, but are exposed to the atmosphere, and this condition has undoubtedly tended to increase the life of the lamps. Each arm is fitted with a 13-in. holophane reflector. While the amount of illumination given by two 100-c.p. lamps is by no means equal to that given by the old arc lamps, yet it is admitted that the amount of effective illumination given on the roadway by the four-arm fittings is at least comparable with that given by the arc lamps, and much better round the base of the post itself. Although up to the present these lamps have been burning for, say, 1,000 hours, the renewals have only amounted to seven out of forty-six, and of these two were broken by the post having been run into.

Careful photometric tests have been taken, and the results show that the same average illumination is obtained at the following average distances:—Arc lamp (17-amp. open-type, opaline globe), 28¼ ft.; four-light fitting, 27½ ft.; and two-light fitting, 21½ ft. The cost of the alteration of the twenty arc lamps to two- and four-arm fittings was £91. This is very low, and is due to the fact that no alteration in the mains was required, as the cables formerly carrying the high-pressure constant current for the series arc lamps were of sufficient cross-sectional area to carry the current at 200 volts for the metallic filament lamps.

The cost of current at 1½d. per unit and maintenance per annum for the arc lamps as compared with the metal filament lamps is shown below:—

Arc Lamps.		*Metal Lamps.*	
Current	£169	Current	£56
Trade account	22	Renewals	29
Wages	61	Wages	7
	£270		£92

In this comparison it is estimated that each metallic lamp will be renewed twice per year, which is undoubtedly higher than will occur in actual practice.

In addition to the economy which can be obtained in the case of arc lamps, it can be proved that the smaller metal lamps can compete against the incandescent gas mantle for side-street lighting. The average candle-power of a 3-ft. mantle does not exceed thirty candles, while with metal filament lamps 30 c.p. can be obtained for 33 watts. At 1½d. per unit, the price per hour for 30 c.p. is 0·05d.; take the price of gas at 2s. 2½d. per 1,000 cub. ft., the cost of 30 c.p. per hour is 0·08d.; so that for 1,000 hours the cost of electricity is 4s. 2d. against 6s. 8d. for gas, but the renewals in the case of electricity (assuming the life of the lamps to be 1,000 hours) cost 3s., and for gas (assuming the life of the mantles to be 400 hours), cost 10d., making the totals, electricity 7s. 2d., gas 7s. 4d., not including extra labour in the renewals of the gas mantles nor breakages of chimney-glasses, nor extra cost of cleaning the gas lanterns.

In this connection the authors draw attention to the fact that in nearly all converted posts the lamps stand up with the lamp-cap downwards, and they suggest that there is a market for a metal lamp in which the leading-in wires are taken to the top of the glass support, and the filament suspended therefrom.

While these alterations were being made in street-lighting arrangements private consumers have not been slow to take advantage of the economy afforded by metal lamps, and a number of installations which had gone back to gas were reconnected. The effect on the supply station at first was not so apparent in the reduction of units sold as in increased illumination. However, as householders began to instal small 25 or 50 volt transformers, a decrease began to be shown. It was then felt that steps ought to be taken to tap that source of revenue which the gas companies have found so remunerative, viz., the class of house which has seldom more than from two to six lamps alight at one time. It was realised that in dealing with small consumers it would be an advantage to have no meters, and to charge on a contract system, and it was decided to offer a contract system of charging on the following terms:—(1) Consumer must supply his own lamps. (2) Each apartment in which a lamp was installed must be adequately lighted by windows in the day-time. (3) The maximum number of lamps to be alight at one time to be declared at the commencement of the contract. (4) The minimum number of lamps applied for to be two and the maximum six, each taking 30 watts. (5) The charge to be 2s. 9d. per quarter per 30-watt lamp, payable in advance.

It has been found that, if builders are induced to wire their houses, the tenants are extremely anxious to avail themselves of the use of electricity; and on one new building estate, where 100 to 120 houses are being erected of the value of £20 per year or less, an agreement to supply on the contract tariff has been entered into, while the builder has agreed to wire the whole of the houses as they are built.

A serious difficulty which had to be faced was the fact that these installations did not warrant anything like the same expenditure on services as has been customary. The average cost of service and the accessories, including meters, in Harrogate for the four years ending March, 1908, was nearly £7. Reductions were made in the following way. The standard practice was to use 7/16s concentric paper-insulated lead-covered and armoured cable, costing about £160 per mile, but it was decided that a 5-ampere cable, costing £50 a mile, would be ample to serve the smaller houses. Then the cut-out box of 25-ampere size, costing 10s. to 12s., was displaced by a smaller box costing 4s. Again, the current limiter only costs 15s., as compared with 35s. to 40s. for a meter. Further, the cost of labour is reduced to one-half of what it formerly was, so that the cost of the new style service for small houses does not exceed 45s. to 50s.

The authors, however, complain that they experienced great difficulty in getting quotations from cable makers for the lighter cable required at prices less than those of the standard 7/16 service cables.

Mr. A. J. Cridge (Corporation Electricity Department, Sheffield) considered that raising the price to compensate for the reduction in the demand caused by the introduction of metallic filament lamps was a short-sighted policy, even if not actually illegal. Referring to the street lighting he suggested that if flame arcs had been substituted for the open type pattern better results would have been obtained. For house lighting he did not advocate using lower than 100 volts with metallic lamps; with 50 volts they had to be very careful to see that the carrying capacity of the wires in installations already in use was large enough to carry the necessary current. His experience of contract rates was very unsatisfactory, he found they were taken unfair advantage of by consumers who neglected to turn off the lights when not required. The fact that consumers were required to supply their own lamps was no deterrent to wastefulness with low voltage lamps as their life was so great. The shunt current of meters was not a serious matter and might be considered negligible so far as it affected the station load. The ideal system in his opinion was not to do away with the meters, but charge a fixed sum on the demand and meter the consumption at a low rate. For heating apparatus he would make a fixed charge of one penny per unit.

Digitized by Google

Mr. S. D. SCHOFIELD (Borough Electrical Engineer, Shipley) asked if Mr. Wilkinson had tried flexible suspension for the incandescent lamps, and if so with what result on the life of the lamps. The system advocated in the paper took no account of heating and cooking. The speaker was meeting with encouraging results in Shipley with regard to heating, but its adoption was handicapped by the fact that duplicate wiring was necessary. In his opinion the "Norwich" system of charging was superior to the one detailed in the paper.

Mr. G. D. A. PARR (The University, Leeds) was surprised to find that the contract system was being revived again, especially in a town like Harrogate. If the cost of prepayment meters could be reduced he should consider their use a preferable system to adopt for small houses. He spoke in favour of the change from arcs to incandescent lamps in the street lighting at Harrogate and considered there would be a distinct advantage in times of fog, as the light from the latter is more penetrating under such conditions. The incandescent lamps were fixed lower than the arcs.

Mr. R. H. CAMPION (Borough Electrical Engineer, Dewsbury) thought the cost of services stated in the paper was high, but this was probably caused by the extra length necessary to supply the large residential houses as compared with a manufacturing town. Holophane shades were very nice when clean, but he found that they soon become covered with an adhesive deposit of dirt which was difficult to remove and which materially reduced the light. The authors are to be commended for trying to reduce the cost of services, but when a departure is made from standard sizes and specifications it is natural to expect to have to pay relatively higher prices. He would remind them that the Northern Counties tried dispensing with meters, but with very unsatisfactory results as the consumers never switched off the light, apparently on principle. Like a previous speaker he did not advocate reducing the voltage below 100, as it would bar the use of heating apparatus entirely.

Mr. H. DICKINSON (Corporation Electrical Engineer, Leeds) was very pleased to see that someone had at last reached the increasing stage again in the current consumption. In Leeds the decrease caused by the introduction of the new lamps, which have been very extensively adopted, would become less each quarter, but had not yet reached the high level of 1907 for lighting current. The reduction in 1908 as compared with 1907 was nine per cent. He would like to know how many lamps were installed on the system advocated; in Leeds they had between 700 and 800 houses at a rental of £20 connected to the mains. The only advantage to consumers in the new system, so far as he could see, would be that they know exactly what they were going to pay. Referring to the sample of service cable exhibited at £50 per mile, he thought it did not look sufficiently mechanical to stand the strain of subsidence in the soil and if put in iron pipes the cost would be materially increased.

Mr. J. W. HAME (Borough Electrical Engineer, York) said that he found the difficulty in regard to new houses was that the bulk of them were erected outside the area of supply, then when the borough increased its area gas was already installed and people would not wire the houses at their own expense. He was gradually coming to the conclusion with regard to a system of charging that it would have to be some method in which measurement of the current was made; any other system was bound to be largely abused by the public. He had been able to bring down the cost of services in York to £5.

Mr. FAWCETT (Harrogate) happened to live in one of the houses included in Mr. Wilkinson's system, and felt grieved that the price charged for his supply was at the rate of 50 per cent. above that of the ordinary consumer. The action of the current limiter he described as diabolical. The system, in his opinion, would never be popular until something slower in action was introduced. The adoption of surface wiring, to reduce the installation cost, is a matter for serious consideration in the question of small houses.

Mr. WILKINSON, in reply, said that the special service cable referred to in the paper proved quite satisfactory in practice. He laid it in special iron pipes with long socket joints instead of screwed joints. This was cheaper than armouring the cable and was quite effective. He had tested the current consumption by meter on the new system and found it was equivalent to threepence per unit throughout the year. He considered that if the lamps were used eight hours per day they would not lose money on the contract. He admitted the efficiency of the arc lamps was not very good, but flame arcs, although good practice in the main streets of a city like Sheffield, would not be suitable for a town like Harrogate. Metallic filament lamps at 100 volts were ideal for such a case and he erected them at a height of 18 ft. He has no experience with flexible suspension.

At present they were feeling their way and going slowly, but they would probably extend the limit of six lamps per house, as they were quite satisfied with the results so far. The service cost of £7 mentioned in the paper included the surveyor's and other charges in making good the streets. The houses fitted were mostly semi-detached, and he was able to make one service serve both houses. They were all on a large estate and had been in operation for twelve months. To introduce a maximum demand indicator instead of a current limiter would be as bad in a contract system as in the tariff system, as a consumer would not know until the end of the quarter what he would have to pay. With reference to heating and cooking he could not see where there was any opening for them in small properties where gas was obtainable.

Mr. McCourt added a few words in reply, saying they had fixed a meter and a demand indicator on the system and found that the diversity factor was 1·8.

ANNUAL DINNER OF THE NEWCASTLE LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS

A VERY successful dinner was held by the Newcastle Local Section of the Institution of Electrical Engineers upon Wednesday, the 15th inst., when upwards of eighty members and guests sat down, the Chairman being Dr. Stroud, of Armstrong College.

After the usual loyal toasts had been given, Prof. R. L. Weighton proposed the "Institution of Electrical Engineers," and spoke of the great changes in advanced technics which the study of electricity had brought about.

Prof. Gisbert Kapp (President of the Institution of Electrical Engineers), in giving the first response to this toast, appeared to be considerably cheered by the lavish use of electric light and power in the Newcastle area, after coming from a locality where people appeared to be very despondent with regard to the present state of the times. He referred especially to the excellent work done by Mr. Charles Merz in utilising the waste gases of the coke ovens, of which the County of Durham abounded. Dr. Kapp referred to the subject of the standardisation of electrical plant on board ship, and said that while in Germany he and others had practically succeeded in persuading the shipbuilders of the Baltic and the North Sea to adopt a uniform standard of voltage, and when he came over to England he endeavoured to get a similar arrangement adopted here. At that time metal filament lamps were coming into vogue, and with this in view the limit of 100 volts was suggested. This was considered by some to be too high, but when affairs seemed to be progressing satisfactorily towards standardisation, the Admiralty suddenly proclaimed a desire for 220 volts. He understood that in the Newcastle area there were two principal standards of voltage informally used for ship lighting, one being 65 volts, and the other 100 volts, and he suggested that the local section could not do better than devote their efforts to obtain a formal standard of some sort amongst shipbuilders and ships in the area occupied by them.

Prof. STROUD, the Chairman of the Newcastle Local Section, who also replied, drew attention to the fact that although Glasgow was the first local section actually commissioned, operations were set in motion for the formation of a local section in Newcastle first of all.

Mr. G. G. STONEY (Messrs. C. A. Parsons & Co.) proposed the toast of "Armstrong College and the Learned Societies."

Prof. HADOW, in response, gave a very humorous account of his impressions of electricity as obtained at Cullercoats, and paid a tribute to the goodfellowship and support which he had received from his staff at Armstrong College. Mr. D. BALFOUR, jun., also responded to the toast as the local representative of the Institution of Civil Engineers.

Mr. C. S. VESEY-BROWN then gave the toast of "The Visitors," coupling with it the names of Mr. Snell, Prof. Bedson, and Prof. Weighton. He also added the members of the Institution of Mining Electrical Engineers who were present, and described them as electricians connected with the most dangerous trade in the country.

In replying to this toast, Mr. J. F. C. SNELL spoke of recent changes in central station practice. Dr. BEDSON noted with satisfaction that electricity was now being very largely used in the chemical industry; and Prof. WELCH drew attention to the great sympathy which existed between electrical engineering and marine architecture.

Prof. W. K. THORNTON replied on behalf of the new Institution of Mining Electrical Engineers, and explained that its purpose was not to trespass upon the domain of the older body, but rather to supplement its work among collieries by first of all educating its own members up to the stringent standard required by the Institution of Electrical Engineers for membership, and also to instruct the mine owners as to the dangers which they ran in appointing incompetent electrical engineers.

Other speakers included Mr. C. Faraday Proctor, the Secretary of the Local Section, who had organised the meeting in a very thorough manner, and Mr. F. O. Hunt, who was responsible for the excellent musical programme.

Tramways and Light Railways Association.—On and after Saturday next the address of this association will be Caxton House, Westminster, S.W. It is proposed to hold the annual dinner and smoking concert some time during the month of February next, and to follow the procedure adopted last year of holding the annual general meeting immediately before the dinner.

CONTINUOUS-CURRENT BOOSTERS AND BALANCERS

At a meeting of the Glasgow Local Section of the Institution of Electrical Engineers on Tuesday of last week, a Paper on the above subject was read by Mr. W. A. Ker. Dealing first with two-wire systems for the sake of simplicity, the author described how series-wound boosters can be used to compensate for the drop in each feeder and to maintain practically constant voltage at all loads at the feeding points. A single machine arranged to compensate for the drop in both positive and return feeders is quite satisfactory with a single feeder, but where there are several feeders connected to one network, it is advisable to employ a separate booster in the positive and return, as otherwise there is apt to be instability and incorrect sharing of the load. Even if this is done, however, care must be taken not to over-compensate for the feeder drop, or a cumulative effect is produced which upsets the sharing of the load. This instability may, however, be obviated by equalising connection between the positive and negative booster field coils, but only at the expense of accuracy of voltage regulation. A better plan is to slightly under-compensate and put up the bus-bar voltage a little at times of heavy load.

The greater number of distribution systems, however, are three-wire, and before dealing with the special points of three-wire boosting, the author briefly considered the principles of the ordinary two-machine balancer. He pointed out how, with plain shunt-wound machines, as the voltage drop across the armature of the machine acting as motor acted in the opposite direction from that of the generator, automatic equality of voltage cannot be obtained unless the field coils be cross connected, and the armature drops compensated for by a few series turns taken from the middle wire. Hand regulation, however, is sometimes used instead of relying on the exactness

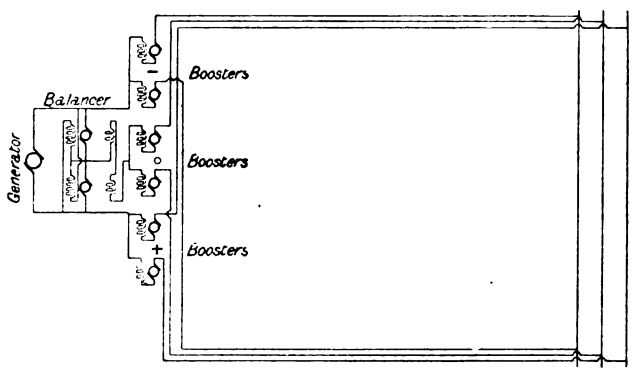

Fig. 1.—Three-wire System with Separate Middle Wire Boosters.

of the design and adjustment of the machines themselves to equalise the voltage automatically. In this case cheaper machines can be employed, as it is no longer necessary to work on the straight part of the curve, but an extra attendant may be necessary.

A cross-connected compound balancer will stand up to any out-of-balance current and strive to keep the voltage equal on the two sides, and this may be a source of danger. If, for instance, a partial short were to occur on one side, the out-of-balance current might become so large that the motoring side of the balancer would be overloaded, causing a flash-over or a breakdown of the motor. To obviate this it is well to put the series coils of the balancer in parallel with a diverter resistance and introduce a fuse, or circuit breaker, into the branch to the coils. In this case, when an excessive out-of-balance current occurs, the fuse will blow, cutting out the series coils, and the balancer will continue to run as a shunt balancer and will be able to deal with a very large current, though naturally the balance between the two sides will be bad.

In large cities it is now the custom to transmit three-phase current to substations at convenient points, and there to convert it into continuous current and transmit it by short feeders to the feeding-points. As these feeders are all short and generally proportional to the load they are expected to carry, all the regulation required is effected by varying the shunt excitation of the continuous-current side of the motor-generators or varying the speed of the motors.

Other towns which supply continuous current direct from the dynamos to the feeders generally raise the pressure of the dynamos as the load increases, and by having more than one set of bus-bars and dynamos different pressures may be carried to suit the load on different feeders. In one case at least not less than seven different pressures were carried in the station at times of heavy load. This system was pronounced by the author to be complicated and uneconomical, as it rendered it most difficult to run the dynamos at their most economical load, and it prevented the use of a battery to assist during the peak load.

Another method of keeping the pressure at various feeding-points approximately constant is to vary the section of the copper in the feeder as the load varies, triple concentric feeders with conductors of three different sections being used, but the

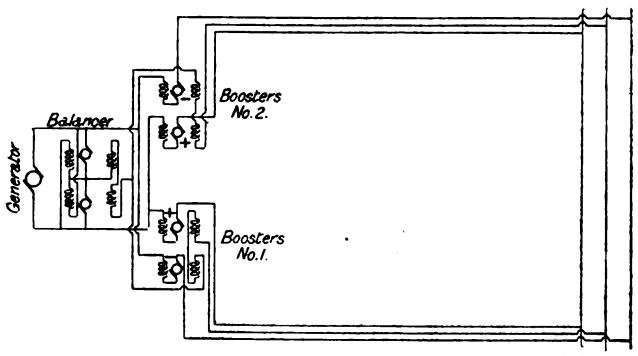

Fig. 2.—Three-wire Boosters with extra Middle Wire Series Coils.

author proceeded to show that the extra capital cost of the multiple feeders and the loss of energy were a serious matter, and much preferred a system of boosters with a constant pressure on the bus-bars. As explained for the case of two-wire working, two separate boosters should be used for each feeder, and they should slightly under-compensate to ensure stability.

Taking the case of a pair of boosters in the outers of a single feeder, combined with a balance at the generating station (which the author much preferred to placing balancers on the network), it was shown that the balancer must itself be designed to compensate for the drop on the middle wire, so that alterations would have to be made to it on the addition of further feeders.

Another plan adopted is to use treble three-wire boosters, each booster having three generators—one in the positive, one in the negative, and one in the neutral, the latter, of course, being electrically reversible. This system, which is shown in Fig. 1, if designed to compensate for the drop in the feeders, is quite stable, and has the advantage that the potentials at the feeding-points are natural potentials, *i.e.*, they are the same amount above and below earth as the busbar potentials. In addition, the load divides between the two boosters in inverse proportion to the resistance of the load from the feeding-points.

Another plan is to use a double booster with each machine,

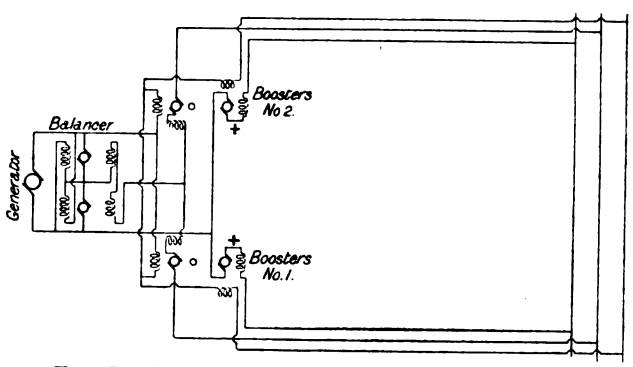

Fig. 3.—Alternative Arrangement of Three-wire Boosters.

fitted, as shown in Fig. 2, with extra series coils, through which the currents in middle wire are taken. The disadvantages of this arrangement are that when the out-of-balance load is much nearer one feeder than the other, the booster of that feeder takes not only the whole out-of-balance load, but it also relieves the other booster of part of its natural load. The copper is therefore not used to advantage, and the boosters must be larger and therefore more costly than they would be if this

Digitized by Google

effect were prevented. Also in certain circumstances serious instability can be produced, so that it cannot be said that this system is satisfactory. Some of these disadvantages are got over by putting the neutral coils of the boosters in parallel, so that the whole out-of-balance current divides equally between them, but the division of the voltage is inaccurate in certain circumstances.

Another system of three-wire booster having only two generators is shown in Fig. 3. There is one generator in the positive which is excited by two coils, one in the positive feeder, and the other in the negative feeder. The positive coil adds the voltage equivalent to the drop in the positive feeder, and the negative coil adds the drop in the negative feeder. The pressure across the outers at the feeding-point is thus always kept constant. There is also a generator in the neutral of the feeder, which also has two exciting coils. One of these coils is the neutral coil, which adds, or subtracts, the drop in the neutral feeder. The other coil is a negative feeder coil, whose function is to raise the voltage of the neutral at the feeding-point by the drop in the negative feeder. These negative coils are equalised as shown. So long as any out-of-balance current is on the positive side, and the other load is equally distributed, the voltage regulation is perfect; but as soon as an out-of-balance occurs on the negative side, or the load centre is not central on the network, that is, as soon as the two negatives carry different currents, the voltage is slightly upset.

All things considered, the system shown in Fig. 1, having three generators, one for each wire, is the most accurate and simple. Its cost is practically the same as that of the boosters with neutral wire coils, as in the one case there are three small generators, in the other case two larger generators with special coils. In one case where the author was quoted alternative prices for the two systems, there was only £10 difference in the cost of the boosters. An additional advantage is, that all future feeders may be ordinary two-wire feeders having two-generator boosters, and the whole system remains stable, so long as the boosters do not over-compensate for the drop.

In a large town the best arrangement is probably to have two three-wire feeders and boosters feeding to fairly widely separated points, equi-distant from the load centre of the network, and to make all other feeders two-wire only. Having two three-wire boosters, one is always available to feed the balancer in case of a breakdown on one neutral feeder or on one of these boosters.

In conclusion, the author touched upon a few points in connection with booster and balancer switchgear.

DISCUSSION.

Mr. Robert Robertson (Messrs. Strain & Robertson, Consulting Engineers, Glasgow) opened the discussion with a eulogy of the Paper, and a communication by Mr. W. W. Lackie (Chief Electrical Engineer, Glasgow Corporation) was then read. Mr. Lackie said that the author had evidently based a good deal of his findings on the assumption that the networks to be dealt with would be connected "solid" throughout. He hardly agreed that this was necessary, and instanced the fact that, at Glasgow, D.-C. feeders (in most cases from sub-stations) feed isolated networks.

Mr. Jas. Caldwell (Messrs. Sayers & Caldwell, Glasgow) said that it was inattention to such important details as those of balancing and boosting that had made certain stations and systems in the United Kingdom the converse of good financial and engineering combinations.

Mr. A. Simon (Electrical Co., Ltd., Glasgow) seemed rather aggrieved because Mr. Kerr had not mentioned such a useful device as the static balancer, and proceeded to give a brief description of its principle. He understood that a variation in voltage of not more than 1·5 per cent. either way could be guaranteed with an out-of-balance current of 15 per cent., and that with 20 per cent. out-of-balance current the variation in voltage would not exceed 2·5 per cent. In referring to three-phase transmission and conversion to D.C., the author had spoken of varying the speed of the three-phase motors. This, he thought, was an error, as it would obviously be very uneconomical to vary the speed of an induction motor, and he drew attention to an arrangement which his firm were now putting forward with a small three-phase booster interposed between the transformer and motor side of converter.

Mr. J. Robertson (Burgh Electrical Engineer, Greenock) thought that three-phase transmission to sub-stations and short D.-C. feeders to distributing network more satisfactory than long D.-C. feeders and boosters. With several such boosters in parallel on such a D.-C. system he would expect trouble. He did not agree with too much automatic regulation; in a station, at heavy load, one might want to alter voltage of one feeder independent of the rest, and automatic regulation would render this impracticable. He would prefer compound-wound machines under control of attendant. He thought one of the principal defects in the balancer design was that of making them too small for their work. Mr. Robertson further thought that too free a use of boosters on feeders would be less economical and satisfactory than good distribution of copper, and he thought that Mr. Lockie's system at Glasgow was wasteful of copper, and that interconnection of copper would give better regulation.

Mr. W. B. Sayers made some remarks on the historical aspect of the subject.

Mr. E. Robertson (Glasgow Corporation Electricity Department) wanted to know if Mr. Kerr would recommend boosters to each feeder in a city like Glasgow. He spoke in favour of static balancers as used on the Glasgow system in outlying districts. On heavy out-of-balance loads, rotary balancers were more used.

Mr. P. F. Allan (Clyde Valley Electric Power Co.) mentioned a case where neglect or ignorance of balancing and boosting principles had led to a serious state of confusion. A large works was supplied from three-wire mains at two points. It was also supplied by a two-wire direct feeder (outers only) at a third point. All three points were interconnected through network in the works, and balancers on artificial neutrals were employed at all three points, as the motors were only 240 volts. The mistake was made of boosting the direct feeder on one outer only, with the result that load was transferred from direct feeder terminals, *via* works network, to town network.

Mr. McWhirter (McWhirter & Son, Glasgow) did not agree with Mr. Robertson (Greenock) in his condemnation of series machines for several reasons. He thought the author's methods excellent where used for supply to long straggling areas, such as a small country township.

Mr. Kerr, in his reply, said that he did not consider such places as Glasgow as towns, and therefore they were not included in the scope of his Paper. With regard to Mr. Simon's remarks on static balancers, as these only act by reason of their inaccuracy, *i.e.*, can only balance by alternating currents flowing from one slip-ring to another, he thought that the figures of voltage variation given were too good to be true. Mr. Kerr didn't agree with Mr. Robertson (Greenock) as to series boosters and balancers. He thought that automatic regulation and the use of series windings gave much finer voltage regulation, and he couldn't see that there was any serious danger to be apprehended.

Lectures on Single-phase Traction.—A special course of advanced lectures and demonstrations on single-phase electric traction will be given at King's College, London, by Prof. Ernest Wilson and Mr. F. Lydall (of Messrs. Siemens Brothers' Dynamo Works, Ltd.), commencing on Monday, January 17th, at 5.30 p.m. The fee for the course is £2 2s. (graduates of the University of London, half price). The first five lectures, accompanied by demonstrations, will be given by Prof. Wilson, and will deal with the fundamental principles involved. The second five lectures, given by Mr. Lydall, will deal with practical considerations with special reference to the Rotterdam Hague Single-phase Railway and the electrification on the Midland Railway.

The Bank Telephone Exchange, Liverpool.—On Saturday, December 11th, at 2.30 p.m., the National Telephone Co. brought into use a new C.B. Exchange called "Bank," which has been installed in a specially designed building in South John Street, Liverpool, to which 1,368 subscribers' lines have been transferred from the Central and Royal Exchanges. The new equipment has been manufactured and installed by the Western Electric Co. of North Woolwich, and is of the No. 1 C.B. type, consisting of 36 "A" positions, giving accommodation for 2,500 subscribers' lines, 12 incoming junction positions, and one exchange testing position. The ultimate capacity of the switchboard is 10,000 subscribers' lines, and the equipment is of similar design to that installed at the company's Altrincham, Birmingham-Midland, Hillhead, Bromley, Dalston, New Cross, and Aberdeen Exchanges.

Birmingham High-Tension Consumers' Dinner.—Those firms who either now take, or contemplate taking, high-tension current from the mains of the Birmingham Corporation electric supply department, were entertained to dinner on the 14th inst., by the leading electrical manufacturers in this city. The hosts comprised the representatives of the following firms:—Messrs. The British Electric Transformer Co., The British Insulated & Helsby Cables Co., British Thomson-Houston Co., British Westinghouse Electric Co., General Electric Co., Hands & Sons, G. Jones, Ltd., and Siemens Bros. Mr. Barker, of the Birmingham Metal & Munitions Co., presided, and Mr. Chattock, Engineer to the Corporation Supply Department, acted as vice-chairman. Speeches were made by the representatives of the various interests present, and it is very evident, from the tenor of the remarks, that cordial feelings of appreciation and goodwill prevail in the three-phase interest of the Corporation as suppliers of energy, the high-tension consumers, and the manufacturers. Mr. Chattock, in his speech, announced that his committee were now considering laying down a central station from five to eight times the capacity of the present station at Summer Lane. This statement should be sufficient to prove to all that matters electrical are in a very live state in Birmingham.

QUANTITATIVE MEASUREMENTS IN WIRELESS TELEGRAPHY

THE two Papers read before the Institution of Electrical Engineers on Thursday last both dealt with the measurement of the efficiency of wireless telegraphic apparatus. The first, by Prof. J. A. Fleming, of University College, contained a mass of information relating to special apparatus and measuring instruments for wireless work, and concluded with an analysis of the energy transformations and losses in the College wireless plant. As a means of measuring the resistance of wires, strips, and spirals to high-frequency currents, Prof. Fleming has devised an apparatus which he terms a differential electric thermometer. This comprises two long glass tubes of large section, closed at top and bottom with mercury air-tight stoppers, and connected by a fine bore tube containing a coloured water thread with an air bubble in the centre. Pieces of wire or strip, the resistance of which is to be measured, are placed in the tubes, and connected through the stoppers, one with a source of high-frequency current, and the other with a source of direct current. The currents are adjusted until equal heat is generated in each tube, this condition being indicated by the bubble in the water thread remaining in the middle of the connecting tube. The ratio of the resistance values will then be inversely as the square of the currents. To measure the current, a special form of hot-wire thermo-electric ammeter was employed. This comprised a number of bare No. 36 S.W.G. copper wires, soldered to end pieces of brass, with an iron-nickel thermo-electric junction attached to the centre of the middle wire, and connected to a galvanometer. For such small wires well spaced out, the ratio of the resistances to high-frequency and continuous currents is unity, and it will read the R.M.S. value of an oscillatory current correctly after having been calibrated by continuous current. The values obtained with this apparatus compared on the whole very well with calculated values. Thus No. 16 S.W.G. gave, with a frequency of 450.000, a high-frequency resistance 4·57 times the normal resistance, while the calculated value was 4·54 by the Russell formula. For bare copper cable (7/22) such as is used for antennæ, the ratio for a frequency of 439,000 was 4·2, and 6·1 for a frequency of 735,000. It was also found with this apparatus that the ratio of the resistance of a spiral of No. 16 S.W.G. to that of the same wire stretched out, was 1·25 for a frequency of 450.000.

Prof. Fleming then described some standard capacities and inductances for high-frequency measurements. Glass, ebonite, and other dielectrics are unsuitable on account of variation of the dielectric constants with frequency. The author's condensers comprise two rectangular sheets of zinc bent into square-cornered spirals, and intertwined so that the surfaces are opposed. These are placed in zinc boxes, and immersed in paraffin oil previously treated with metallic sodium or potassium to remove all moisture. The capacity of such a condenser is determined at a low-frequency of 100, and can be assumed to be the same for all frequencies up to a million or more. Standard inductances for use with these capacities comprise a rectangle of copper-wire fixed in a groove on a wooden board. One rectangle of moderate dimensions associated with a number of standard condensers will cover the range of frequency required for wave-meter calibration. The author gives formulæ for predetermining the inductance of single-layer solenoids of various forms, and points out that for the same mean radius and turns, a circular coil wound radially has the same inductance as when wound cylindrically. Some convenient forms of variable inductances without sliding contacts, consisting of spirals movable relatively to one another, are described in the Paper. A pair of flat spirals moving over one another with planes parallel gives a variable mutual inductance from maximum down to zero with very little movement.

It is essential to be able to count the spark frequency in wireless measurements, and Prof. Fleming describes a photographic counter comprising a sliding sensitive plate on to which is projected the spark image through a lense by a rotating prismatic mirror. The instrument is calibrated by rotating a pierced disc before an arc at a known speed. A large number of records taken in this way are given in the Paper. With a long spark of 5 or 6 mm. from a transformer, there is one spark every half-period, but if much inductance is introduced into the low-tension side of the transformer, each alternate discharge is suppressed. With a 2 or 3 mm. gap, there are from 3 to 5 sparks each half-period, and with smaller gaps still there is an almost uninterrupted train of discharges. These results, continues Prof. Fleming, show the futility of all plans for effecting resonance between two stations by syntonisation of the spark frequency, and not the oscillation frequency.

After describing methods of measuring the wave length and the damping or logarithmetic decrement in both sending and receiving antennæ, the author turns to the measurement of the efficiency of a wireless plant, *i.e.*, the ratio of the watts emitted by the antennæ as waves to the mean power given to the transformer. Knowing the spark-frequency, the mean pressure and the capacity of the condenser, the power given to the condenser circuit can be readily determined, and by subtracting from this the various C^2R losses in the condenser and antenna circuits, the remaining emitted power can be estimated. The following were the various figures arrived at for the University College plant:—Spark frequency = 208; capacity of condenser = 0·0139 m.f.; spark voltage = 17,500 volts; oscillation constant = 6·9; current in condenser circuit, R.M.S. value = 26·5 amperes; mean wave length = 1,350 ft.; decrement of condenser circuit = 0·0507; antenna current, R.M.S. value = 4·9 amperes; high-frequency resistance of antenna circuit, 0·528 ohms for jigger secondary circuit, 0·21 ohms for antenna proper; length of whole antenna = 195 ft., 4 branches. The transformer input was 800 watts; 445 watts were delivered to the condenser, and the primary oscillation circuit losses were 351 watts, so that 94 watts were delivered to the antenna. The antenna resistance losses were 16 watts, leaving 78 watts as the power radiated. This gives an efficiency measured from the transformer intake to radiation of 10 per cent.

The efficiency of reception is necessarily very small, continued the author. In a certain case of a 50 metre high, 4 mm. antenna on the French battleship *Henri IV.*, with a similar receiving antenna, with the antenna charged 20 times per second with a 5 cm. spark, the mean radiation was 36 watts, or $1·8 \times 10^7$ ergs per spark. At a distance of 1 km., the energy picked up was 320 ergs per spark or 6,400 ergs per second. The captured energy was thus about 1/600 of 1 per cent. of that sent out, and since this latter was at most 5 or 10 per cent. of that given to the transformer, the overall efficiency was very small indeed. Finally, Prof. Fleming pointed out that the radiation from a vertical antenna is a maximum in a horizontal direction, and 1·5 times the mean spherical radiation intensity. This is a valuable property, as the energy is radiated chiefly along the earth, and not up into the sky.

Dr. W. H. Eccles and Mr. A. J. Makower described the results of experiments made to determine the efficiency of a wireless plant employing a short spark discharger of the type used by Lepel. This comprises two parallel surfaced copper plates between which the discharge passes, and which form the opposed faces of two metal boxes. These boxes are cooled by water flowing through them, and the surfaces are kept apart by one or two paper rings of a thickness depending on the voltage and the current required.

For the purposes of wireless signalling, continue the authors, the discharger is connected as shown in Fig. 1, in which *I I* represent choking coils, *R R* regulating resistances, and *S* the

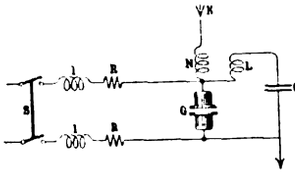

FIG. 1.—FOR SIGNALLING.

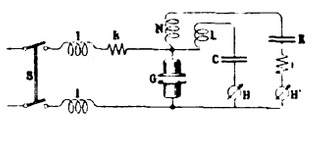

FIG. 2.—FOR MEASURING EFFICIENCY.

CONNECTIONS OF OSCILLATORY CIRCUITS.

main switch. The primary oscillating circuit is formed by the inductance *L* and the capacity *C*, and the secondary circuit by the aerial conductor whose capacity to earth is *K*, the inductances *N* and *L*, and the condenser *C*. The last-named path must be tuned by trial to the oscillating circuit *L G C*. The secondary is associated with the primary, first, by the direct coupling at *G*, and secondly by the mutual inductance coupling between *N* and *L*. The two couplings must be connected so as to conspire. The primary condenser must be of considerable capacity, for the supply pressure is usually of the order of 500 volts. Only a fraction of the total energy taken from the supply circuit is received at the gap terminals, and only a fraction of this again will be received into the secondary circuit or aerial. Of this last portion some will be wasted ohmically, but most will be radiated.

As there is no direct way of measuring the energy radiated from an aerial wire, the authors used a special resistance instead

Digitized by Google

of an aerial for dissipating the energy, it being known that the energy radiated from an aerial can be represented by the heat generated in a series resistance of 30 to 60 ohms. The resistance possessed a high-frequency value of nearly 40 ohms; it was connected in the secondary circuit as shown in Fig. 2 at r. The capacity of the aerial was at the same time replaced by an air condenser K. H and H^1 are hot-wire ammeters used merely as indicators. The resistance r was placed in a small calorimeter containing paraffin oil and provided with a stirrer and delicate thermometer. The ballast resistance R in the main circuit consisted of Eureka wire wound on a frame, and placed in a calorimeter containing paraffin oil. The calorimeters enabled the energy passed on to the secondary circuit as electrical oscillations and the heat wasted in the ballast resistance to be measured simultaneously. The heat wasted in the arc was measured by taking the difference between the temperature of the water flowing in and that flowing out. The electrical dimensions of the apparatus were:—L=8·0 microhenries; N=171 microhenries; C=0·041 microfarads; K=0·0019 microfarads. r had a high-frequency value of 38 ohms and a negligible inductance. R was given different values. The supply voltage was 500 volts. The frequency of the oscillations was 294,000 cycles a second, and therefore the wavelength was 1,020 meters.

The efficiencies obtained, excluding the losses in the ballast resistance R, were from 35 to 49 per cent., while the overall efficiencies, including the ballast resistance losses, varied between 4·6 and 14·4 per cent. The values become lower the greater the current. This was perhaps due to the difficulty that was experienced in keeping the arc in an active condition throughout a run. The difficulty was overcome by rotating one of the electrodes as soon as the oscillations showed signs of dying out.

DISCUSSION.

Mr. J. E. Taylor (General Post Office) said that Prof. Fleming had not stated what degree of accuracy was obtainable with his method of measuring the high-frequency resistance of conductors. He presumed it was not very accurate yet, but he appreciated the difficulties that had to be overcome. His results showed that it was not a very accurate method. The higher frequency in one case gave a lower high-frequency resistance than the lower, which was not consistent with the calculated values. In other examples, the discrepancy was greater; he was therefore inclined to doubt the figure given by the author of 78 watts as the amount of power radiated from the antenna at University College. His main reason for doubting this was that the total high-frequency resistance of the antenna circuit was given as 0·528 ohms, and only 0·21 ohms for the antenna proper. This latter might be correct so far as the copper losses in the antenna were concerned, but surely it left out the losses at the earth connection, and also the dissipation losses after the current had left the earth plate. There were other losses due to electrostatic induction in conducting masses, such as pipes and wires. He thought the actual balance available for the antenna was probably a great deal smaller than the amount given in the paper.

Prof. Ernest Wilson (King's College, London) suggested that licences for wireless telegraph installations should be regulated by the amount of energy put into the ether by the system adopted, and, in this connection, the Papers enabled the Post Office to form a very good idea of this amount. With regard to the condensers, eddy currents were set up when the plates were traversed by high-frequency currents, and consequently the distribution of current in the plates themselves would not be uniform. Probably one or two matters of this sort might affect the figure of 78 watts.

Prof. J. T. Morris (East London Technical College) asked if Dr. Eccles and Mr. Makower had measured how the efficiency varied with the length of the spark; also whether any experiments had been made with regard to the medium in the gap. He showed three lantern slides in this connection, showing arcs burning in air, in coal gas, and in amyl-acetate. These slides showed that when using coal gas there was a very steep rise in the voltage up to a sharp peak, and then it suddenly dropped away in an extraordinarily short time, when the current rushed through the arc. The use of amyl-acetate showed a similar result compared with air. All these experiments were carried out at a frequency of 50 cycles per second, and no doubt there would be a totally different result with a frequency of 1,000,000 cycles per second. Other experiments had also been made at the East London College by Mr. H. J. Warren and himself, the results of which he showed by diagrams. These showed that with paraffin oil in the spark gap instead of air, about thirteen times the energy was taken up by the receiver. The most efficient gaps were as follows:—Paraffin oil, 1/100 mm.; amyl-acetate, 1/400 mm.; air, 400 mm.

Dr. J. Erskine-Murray thought it probable that Dr. Fleming had overlooked two sources of error in his differential thermometer for measuring resistances. The diagram showed an induction coil, coupled directly to the apparatus. The result was that the wire carrying the high-frequency current had alternately low-frequency current and high-frequency oscillations passing through it, instead of a continuous flow of oscillations. The difference in effect might be 5 or 10 per cent., depending upon the damping of the train of waves. The second source of error was likely to counterbalance the first one, and was due to the fact that the waves were damped, and that the resistance obtained would be higher than for undamped waves. Calculation had shown the difference to be about 4 per cent. The results with Dr. Fleming's photographic recorder were not so good as those taken on a cinematograph. Prof. Majorana had attempted to obtain a high spark rate by using a special square A.-C. wave-form, but had not been very successful. Dr. Eccles' experiments showed a very satisfactory efficiency, and it was certainly an advance upon the spark method. They had used, however, direct-current with both electrodes of copper. It was more efficient to use one electrode of hard brass or Delta metal and the other of copper. The condenser they used was not nearly so large as that used in other systems. The Lepel condenser was fully ten times as large. There did not appear to be any inductance in the substitutional circuit, and this should tend to reduce the efficiency again. Another point was the use of Eureka wire as resistance. This had no temperature coefficient, and seemed to him to be the very worst wire that could have been used.

Prof. Fleming, in a communicated reply, asserts that Mr. Taylor did not offer sufficient reasons for his doubts as to the accuracy of the measurements, and explains that the discrepancies in the measurements of high-frequency resistance by the differential thermometer could be traced to the high-frequency ammeters. With improved ammeters, better results have been obtained. Dr. Fleming admits that there may be additional losses in the earth connection, and describes how they can be measured, but he does not attach much importance to them. He also thinks that losses by electrostatic induction can be avoided. The object of the Paper was, he writes, to show how the energy radiation could be measured by difference. With regard to the difference in resistance with damped and undamped oscillations, mentioned by Dr. Erskine Murray, Prof. Fleming asserts that the difference in the results is not so great as stated. He denies that similar spark photographs to those he showed have ever been taken before, as the diagrams in Dr. Ruhmer's book seemed, he says, to be the product of the imagination. He agreed with Prof. Wilson that the permissible radiated energy should be defined when granting licences. It would not do to reckon only the power given to the apparatus. He also notes with pleasure that the results of Dr. Eccles and Mr. Makower agree fairly well with his own, and hopes that the papers will prevent exaggerated claims for efficiency, and clear the way for more complete scientific knowledge.

Dr. Eccles, in replying to Prof. Morris as to experiments with various lengths of gap, said that they had merely found out the one which gave the best result for their purpose. In reply to Dr. Erskine-Murray, they had tried hard brass for one of the electrodes, but could not appreciate any difference. With regard to the size of the condenser, this was copied from the Lepel installation at Slough.

In a written communication, Mr. B. Davies doubts the conclusion of Prof. Fleming that resonance between two stations by syntonisation of the spark frequency is impossible. He thinks that, with a low spark frequency, proper relation between spark length and the E.M.F. of the charging circuit, and the avoidance of ionisation in the gap, only two sparks per period are possible. With regard to the relative inductance of cylinders and spirals, he thinks that the former should possess a larger inductance. Finally, he calls attention to the great sensibility of a coherer, as shown by the energy figures given for the battleship *Henry IV.* experiments. These give a "power attenuation" constant of 20 per mile, as against 0·01 per mile for a submarine cable working at top speed.

We have received the following communication on the subject from Mr. C. C. F. Monckton:—The Paper by Professor Fleming before the Institute of Electrical Engineers was very suggestive as an attempt at quantitative measurements. It is a pity, however, that the already published mathematics were not omitted, and that the experimental results were not given in greater detail. The differential electric thermometer was worth a Paper by itself. As it was, this instrument received some criticism, and it is to be hoped that Prof. Fleming will give more details of his measurements with this instrument. It appears to the writer that the resistances measured in the experiments were the effective resistances in a simple oscillatory circuit as originally used by Marconi and still used by Lodge. As an alternative, the resistance might have been placed in a secondary circuit coupled by a Tesla transformer, and the effective resistance measured, using induction coil, transformer, and Wiren sparks in turn to produce the vibrations. The engineer requires the resistance for the particular system he is using. It may be that Prof. Fleming has tried all methods, and found the difference negligible; it would be interesting to know. More data are required to show that the ammeters and standard oscillation circuit are correct.

THE INSTITUTION OF MINING ELECTRICAL ENGINEERS

THE inaugural general meeting of the new Institution of Mining Electrical Engineers was held on Friday last at the Midland Hotel, Manchester. There was an attendance of some ninety members, and the chair was taken by Mr. W. Maurice, General Manager of the Hucknall Torkard collieries, Nottinghamshire, and first President of the Institution.

The Institution has been founded to augment the safety and promote the advancement of knowledge relating to the application of electricity in mining, to extend the experience and increase the efficiency of those engaged in such applications, and generally to form a meeting-point for a rapidly growing but hitherto unorganised section of electrical engineers. Branches have been established in Newcastle-on-Tyne, Leeds, Manchester, Nottingham, Birmingham, London, and Cardiff, and others may be formed, in Great Britain and abroad. Papers will be arranged to be read simultaneously at all the branches, and all Papers will be published in the *Iron and Coal Trades Review*, which will be sent free to all Members. Membership is at present open to any person above the age of 23, who, as mine manager, colliery engineer, or otherwise, is associated with electric mining work in a responsible capacity. Associateship is open to all classes of mine officials who are not eligible for membership, to assistant electricians, electrical and mining students, and apprentices. Under the new rules, which will shortly come into operation, the age limit will be raised and the conditions of membership will become more stringent. A diploma class of membership for those who desire some form of evidence of competency to take charge of electrical plant in mines, is to be established. Admission as a diploma member will only be obtainable after examination by an independent examining board appointed by the council. The fees are:—Members, £1 1s. per annum; Foreign Members, £1 6s. per annum; Associates, 10s. 6d. per annum, payable in advance, and it is proposed that an entrance fee shall be paid by all members joining after July, 1910.

At the Council meeting previous to the general meeting, the following gentlemen were present:—Mr. W. Maurice (Chairman), Mr. Roslyn Holiday (Acton Hall Collieries, Featherstone), Mr. E. Ivor Davies (Llandebie, Carm.), Mr. Sydney F. Walker (Bath), Mr. W. C. Mountain (Messrs. Ernest Scott & Mountain, Ltd., Gateshead), Prof. W. M. Thornton (Armstrong College, Newcastle), Mr. H. J. Fisher (Lambton Collieries, Durham), Mr. H. W. Clothier (Messrs. Reyrolle & Co., Newcastle), Mr. J. H. C. Brooking (St. Helens Cable Co.), Mr. G. Glynn Williams (Moresby Coal & Iron Co., Whitehaven), Mr. J. H. Winstanley (Mining Dept., Manchester University), Mr. P. D. Coates (Burnley), Mr. R. Krall (London), Mr. R. H. Haggie (Wealdstone), Mr. R. J. Frost (Bentley Collieries, Doncaster), Mr. F. Cusworth (East Kirkby), and Mr. S. H. Bill (Barnsley). The members of council not present were:—Mr. H. Arnott (Bedworth), Mr. A. Hall (Nuneaton), Mr. F. O. Kirkup (Garesfield Colliery, Newcastle-on-Tyne), and Prof. W. Robinson (University College, Nottingham).

The following officers have been elected for the various branches:—*Newcastle-on-Tyne:* Pres., Mr. F. O. Kirkup; Sec., Mr. H. J. Fisher; *Leeds:* Pres., Mr. R. Holiday; Sec., Mr. R. J. Frost; *Lancashire, Cheshire, and North Staffordshire:* Pres., Mr. J. H. Winstanley; Sec., Mr. P. D. Coates; *Derbyshire and Nottinghamshire:* Pres., Mr. W. Maurice; Sec., Mr. F. Cusworth; *Warwickshire and South Staffordshire:* Pres., Mr. A. Hall; Sec., Mr. H. Arnott; *South Wales:* Pres., Mr. S. F. Walker; Sec., Mr. E. Davies; *London:* Pres., Mr. Hood Haggie; Sec., Mr. R. Krall.

Before delivering his address, the President announced that the following officers had been elected for the present session:—Vice-presidents: Mr. W. C. Mountain and Prof. W. Robinson; Hon. Editor of Transactions, Mr. J. H. C. Brooking; Treasurer, Mr. J. Glynn Williams; President of Finance Committee, Mr. A. M. C. Field, of the Consett Iron Co., Newcastle; General Secretaries, Messrs. Saunders (Bank Chambers, London Road, Derby). Mr. R. Nelson (H.M. slectrical Inspector of Mines), and Mr. J. Glynn Williams (principal founder of the Institution), were elected honorary members. It was also announced that Mr. J. Kirkby (Chesterfield) had offered an annual prize of two guineas for the best invention connected with the use of electricity in mines. The prize is open only to members of the Institution, and is to be awarded by the Council.

The President opened his address by referring to the founding of the Institution in April last as an independent body, and not as an offshoot or a rival of any existing association. So recently as 1889, there were only three or four electrical power installations in the mines of this country, and only forty-two mines had adopted electric lighting; to-day, he said, practically every colliery in the country had its own generating station. Referring to the benefits which all classes of colliery employees derive from the introduction of electrical methods, Mr. Maurice pointed out that the miner had been the gainer to a surprising extent, both in material prosperity and in the amelioration of the conditions of labour. He now earned considerably more than he did before the introduction of electrical methods, and the demands on his physical powers were lessened. Though it might appear that machinery had displaced the hand-worker, the use of machinery, Mr. Maurice said, often made it possible to work otherwise wholly unprofitable seams, and always increased the total volume of unemployment.

Turning to the relative importance of the various mine officials, the President said that the Royal Commission might well recommend some changes in the disposition of legal responsibility with regard to engineering matters. At present, the administrative department of a colliery consisted of the owners or a board of directors, the agent, and the general manager, these being seconded by a large group of departmental managers. The owners or directors controlled the broader lines of policy of the company, the agent conducted the commercial affairs, and the manager controlled the technical department. The manager must hold a certificate granted by the Secretary of State, after his examination by a Board composed of three owners, three workmen or persons originally workmen, three mining engineers, agents or managers, and one inspector of mines. This constitution had, said Mr. Maurice, worked satisfactorily for many years, but a very high standard of attainments was now demanded of the colliery manager, and it was expected that the next Mines Act would make a "clean sweep" of the entire system. The training and qualifications required of a mine manager in South Africa were much ahead of home requirements. In the absence of the manager, the under-manager assumed his responsibilities, and was legally responsible for all non-compliance with the General Rules. The engineer, the electrician, and all other officials, were responsible to the manager or the under-manager, and the latter, especially, was brought into close contact with the electrical department, because he was immediately responsible for the signalling arrangements. The engineer was, unfortunately, not sufficiently recognised, and he appeared to have missed the opportunity of presenting his case to the Royal Commission. The same could be said of the electrician.

Mr. Maurice next touched upon the difficult relationship between the colliery engineer and the electrical engineer. Both, he said, were destined to become mining electrical engineers, and should seek to understand each other. It was natural that the experienced colliery engineer should resent the intrusion of electrical methods, but electrical methods meant efficiency, and had to be adopted. In the future, both must understand even more of mining, and to the colliery engineer a knowledge of electrical work was now essential. There was a strong feeling that colliery engineers should be certificated, and the necessary training and preparation to obtain a formal qualification tended, he thought, to produce the right class of men. An improvement in the position of the engineer would do much to lessen accidents. If the electrical engineer were made responsible for the maintenance of the electrical plant, it would improve both the installation and the engineer.

With regard to the membership of the Institution, the President said that colliery engineers were eligible, and could qualify for diploma membership. Colliery managers would be valued members, and no class of official or member of a colliery staff was inadmissible. He suggested that college branches should be established to bring mining and electrical students into touch with the work. The transactions of the Institution would be published in the *Iron and Coal Trades Review*. Anyone who claimed to be a technical man, continued Mr. Maurice, must read the principal journal or journals relating to his business; and mining electrical engineers must read electrical journals as they dealt with their own special department.

Turning to the risks attending the application of electricity to the mining industry, Mr. Maurice said that the probably erroneous inference amongst the public that electricity was the prime cause of the recent disastrous explosion in the North, had created an impression that electricity was dangerous in mines. The Institution would enter upon an inquiry into electrical accidents, and thus endeavour to allay public anxiety. The rest of the President's address was intended especially for the younger members of the Institution, and dealt with the influence of character on work. The safety and even, perhaps, the economy with which electricity could be used in mines was, he said, primarily based on character. During the period from 1903 to the first half of 1909, there were 48 accidents from shock, causing the death of 51 persons, and 19 electrical ignitions of firedamp, resulting in the death of 16, and injury to 33 persons. Of the 19 ignitions, 14 were attributed to defects, the cause of which might be divided equally between unsuitable apparatus and neglect, and of the 48 accidents from shock, 37 were assignable to carelessness. In an analysis of electrical breakdowns by one author, rough usage and defective attention accounted for 23 per cent. of the failures, while Mr. Longridge had shown in his report for the British Engine, Boiler, and

Digitized by Google

Electrical Insurance Co., Ltd., for 1908, that the proportions of breakdowns due to dirt and neglect were 23 per cent. for generators, 30 per cent. for motors, and 17 per cent. for starters. More careful attention to plant, or, in other words, an improvement in character of the men in charge, was highly important. As President, he looked to the members to improve their own status, and thereby the status of the Institution.

In proposing a vote of thanks to the President, Mr. W. C. Mountain said that he had been connected with the application of electricity to mining for 25 years, and believed that all the trouble which arose was from a want of knowledge of how the work should be attended to. If electricity was properly used it was the safest power for mines, but it was certainly dangerous if badly looked after. The Institution should be a means of bringing men together to discuss and arrive at practical solutions of the difficulties met with. The proposal was seconded by Mr. S. F. Walker, and carried with acclamation.

An informal discussion (which the press were requested not to report) also took place on the advisability of making a change in the name of the Institution. Reference to this is made in a letter by "H. W. C.," which appears on another page of this issue.

A dinner was held subsequently in the Midland Hotel, and was attended by close on one hundred members and guests. In proposing the toast of "The Institution of Mining Electrical Engineers," Dr. Thornton referred to the comparative merits of A.-C. and D.-C. working. Personally he thought that, at present, polyphase working was the most suitable for mines, but he looked forward to the time when single-phase plant would be used. When effectively and properly used, electricity was a great boon to the miners, and actually increased the safety of working. Finally, Dr. Thornton paid a tribute to the pioneer work of Mr. Williams and the President in connection with the Institution.

The President, before replying, read a telegram from Mr. R. Nelson, regretting his absence, and wishing the Institution success. The Institution, said Mr. Maurice, was officially recognised as a body likely to prove of considerable service to the mining industry. With regard to their relation to the other institutions, there was only one institution which could make or mar them, and that was the National Association of Colliery Managers. He had met the Council in London, however, and they were very sympathetically disposed. Concerning the relative merits of A.C. and D.C. working, he had just installed a D.C. extension to an A.C. plant, and he thought the combination of the two was the most economical. It was more a question of safety than of economy, however, and he thought that it was possible that the result of the coming investigations would be that A.C. working would not come out on top.

Mr. J. Winstanley proposed the toast of the "Mining Industry," emphasising the high importance of the industry, and the adaptability of electrical engineering to coal mining. Mr. W. Ritson, of Manchester, and Mr. Holiday, responded to the toast, the latter, manager of a large colliery, stating that the prayer of the mining engineer was that they might be saved from more legislation. The first few broad rules would be enough together with inspectors. He did not know whether to be thankful for the coming revision of the rules or not. Mr. Brooking then proposed the toast of the President, and in replying to this, Mr. Maurice said that as yet they had not got hold of the colliery engineers, but that they hoped to.

A number of members of the Institution paid a visit to the works of the Westinghouse Manufacturing Co., at Trafford Park, on Saturday morning.

The Central.—The December number of the magazine of the old students' association of the City and Guilds of London Central Technical College Old Students' Association, contains a number of articles on engineering subjects. Among those of electrical interest are "Impressions of an Eastern Electric Tramway," by R. L. Griffin, and an article on the "International Electrotechnical Commission," by Mr. C. le Maistre. Several books on electrical engineering matters are reviewed.

Underground v. Overhead Telegraph Wires.—In the Sheffield Stipendiary Magistrate's Court last week, a case was heard between the Postmaster-General and the Corporation in regard to an application by the former for permission to erect 42 telegraph posts in Carlisle Street and Carlisle Street East, Sheffield. The Corporation strongly opposed the application. On behalf of the Postmaster-General, it was pointed out that the cost of placing the wires on posts would be £343, whilst if they were put underground the cost would be increased to £1,456. The Corporation, in addition to objecting on æsthetic grounds, urged that the construction of tramways in the thoroughfares referred to, which was very likely to take place in the near future, was a good reason why poles should not be erected. The presence of the telegraph poles would then constitute a danger to the public. It was also pointed out that there was more danger of overhead telegraph wires collapsing through corrosion in a district like Sheffield than in districts with less polluted atmosphere. Eventually the magistrate decided in favour of the Postmaster-General.

LOADING COILS FOR TELEGRAPH AND TELEPHONE CABLES

Failure of Opposition to a Patent

THE Comptroller-General has decided to allow the grant of a patent to Messrs. Willoughby S. Smith and W. P. Granville for a method of manufacturing flexible inductance coils for insertion into telegraph and telephone cables at intervals along their length in the course of manufacture. It will be remembered that the grant was opposed by Messrs. Siemens Bros. and Co., who alleged that the invention had been anticipated by a patent granted to them conjointly with Mr. William Dieselhorst, and partly communicated from abroad by the Siemens and Halske Akt.-Ges. Further, they asserted that Messrs. Smith and Granville's invention was not sufficiently described in their complete specification. The two specifications concerned were given, together with claims and drawings, in ELECTRICAL ENGINEERING, September 9th, 1909, p. 791.

Messrs. Smith and Granville's specification is numbered 27,470 of 1908, and describes the following method of construction. A number of insulated wires are stranded over an insulating core, and iron wire is coiled transversely over these wires for a certain length. More insulated wire is stranded over the iron wire, and the ends of the inner and outer layers of insulated wire are joined so as to make one continuous coil. There may be two windings on the annular iron core. In the case of a four-conductor cable, two conductors are carried straight through the central core, while the others are connected at each end of the coil to the two windings.

The inductance coils described in Messrs. Siemens Bros.' patent No. 25,306 of 1906, are also annular in construction. Insulated wire is wound axially on short iron cylinders, and the main wires not connected to a coil pass through it. Flexible distance pieces of rubber are placed between adjacent coils to give flexibility, and the whole is encased in a tube of insulating material joined to the cable at each end.

At the hearing before the Comptroller, Mr. Moritz appeared for Messrs. Smith & Granville, and Mr. Gray and Mr. Hume for Messrs. Siemens Bros. & Co., Ltd., and W. Dieselhorst. Mr. Moritz argued that the problem solved was that of supplying a cable with inductance coils which shall have as far as possible the flexibility of the cable itself. The applicants had solved the problem in one way, the opponents in another. The applicants claimed a flexible inductance coil made by stranding or twisting together with a helical lay inner and outer wires around a core of coiled iron wire, while the opponents had claimed an assemblage of individually rigid inductance coils having flexible distance pieces inserted between them. He pointed out that the assertion by the applicants in their declarations that the individual inductance coils of the opponents' invention were rigid was uncontradicted. Mr. Gray argued that the wires of the applicants' coil passed along parallel to the axis of the coil, and that nowhere in the specification was it stated that the wires were wound helically. He contended that Messrs. Siemens Bros. & Co. had in their claim 2 claimed broadly the inclusion in a cable of an inductance coil, covered with flexible insulating material, and that they were the first to show such a construction. What the applicants did was substantially the same. He asked, therefore, for the insertion of a specific reference in the applicants' specification to the opponents' patent.

The Comptroller states that he is unable to agree with Mr. Gray that the applicants have not described a flexible coil made with wires twisted together in a helical manner. They have stated, he says, in their specification that the coil is formed as a cable by ordinary cable-making machinery, that the inner and outer wires are twisted together, and in claim 1 the coil is said to be formed by "laying" a number of insulated wires around the iron coils. I understand, he continues, the word "lay" to be used in its ordinary technical sense in rope or cable making, and I conclude therefore that the wires are twisted together in a helical manner, so giving flexibility to the coil. I find also that the opponents' claim 2 is a detailed claim for a specific way of encasing inductance coils in flexible insulating material to form part of a cable, and therefore that the opponents are not entitled to a broad interpretation of this claim as against the applicants' claims. The idea of covering inductance coils by insulating material was not new at the date of the opponents' patent, and is shown, for example, in Shoemaker & Gehring's patent, No. 13,881 of 1901. I am of the opinion, therefore, that no addition of a specific reference, nor other amendment of the applicants' specification is required. The patent will therefore be granted, and the opponents have been ordered to pay the applicants the sum of twelve guineas in respect of costs.

THE GERMAN ELECTRICAL INDUSTRY

Manchester Discussion

THE Paper entitled, "Notes on Methods and Practice in the German Electrical Industry," by Messrs. L. J. Lepine and A. R. Stelling, which was read on Thursday, December 9th, before the Institution of Electrical Engineers, in London, was also discussed in Manchester on Tuesday, December 14th. In the Paper, a long abstract of which was given on page 1057 of our last issue, the authors compared the principal features of German and English manufacture and design of electrical machinery. They considered the following factors contributory to the success of German manufacture:—Commercial enterprise, good general management, close study given to schemes, large capital, and backing by banks. The two-shift system, cheap labour, and thorough specialisation, are also important factors in competition. In design, they said, England is in no way behind, in fact, in several cases the English designers are more farseeing, and their designs are more practical than those of their German competitors.

The Manchester discussion, which was devoted more to the actual subject of the Paper than was the discussion in London, was opened by Mr. J. S. PECK (British Westinghouse Co.), who compared the German methods of financial development with those which had been adopted in America. Referring to the remark about the working day that it is divided into two shifts of nine hours each, he understood that the A.E.G. worked three shifts of eight hours each. It had been stated in the Paper that the German workman was not so careful with his work, and that the windings had a slovenly appearance, and he thought that was true in general, but had seen some machines of German make beautifully finished. He had been through a large electrical works with the managing director of one of the four companies mentioned in this Paper, who had said that in some respects the British work was not up to the German, but in general was very much impressed with the quality of the workmanship that was being put into the apparatus, and said that they could teach us nothing with regard to high-voltage windings.

Mr. GREGORY (Lancashire Dynamo & Motor Co.) criticised the practice of not allowing draughtsmen to enter the shops, and thought that the reasons why English firms had not such fully equipped agencies was bound up with the financial question. He also asked for further particulars of the *Kollonnen* piecework system.

Mr. T. L. MILLER (Messrs. Miller, Wilson and Pegg) dwelt upon the financial methods and the complete staffs kept in foreign countries, and considered that both these points had great influence on the manner in which Continental firms have obtained large contracts outside their own country and in competition with British manufacturers. He agreed that, as regards the design and construction, British firms have nothing to fear from Continental firms. A similar piecework system to that described was in use in many shipbuilding yards. With regard to management of works, he was also in favour of draughtsmen keeping in touch with the manufacturing as well as costing departments. He then proceeded to describe a system of management in use in a well-known engine works in the Midlands, where there were four separate committees on designs estimating and costs, works, and sales.

Mr. J. FRITH wished to know whether, in the curves, comparing English and German machines, allowance had been made for the fact that the German machines were allowed 80° F. rise, whilst the English would only rise, say, 70°, and also take a larger overload. If this had not been done, the difference would be even more in favour of the English design.

Mr. K. M. FAYE-HANSEN (British Westinghouse Co.) agreed that the success of the German manufacturers was not a matter either of tariff conditions nor designs. There were many smaller firms doing important work as well as the four mentioned in the Paper; for instance, the Körting & Matthieson Co. were probably turning out as many arc lamps as any of the large firms, and he thought that the continued existence of many of the small firms was one of the reasons why the Trusts in Germany had not been detrimental to the German electrical trade, as competition in all classes of work had prevented the stagnation which otherwise probably would have taken place. Regarding internal organisation, the authors had got either wrong information or had generalised from some special works. For instance, it was not true that all engineers went through one of the drawing offices, nor was subdivision carried out to such an extent as would be believed from the Paper, except in the very largest firms. The forbidding of draughtsmen to enter the shops was certainly not universal, nor was the two-shift system. German manufacturers when pressed were quite as willing as any English firm to alter their standards if an important order could be obtained. The German requirements, however, were very much more uniform, due to the existence of the recognised German Normalien, and due to the fact that relatively few independent consulting engineers existed in that country.

Mr. R. B. SLACKE (Key Engineering Co.) said that a German works with which he was connected paid wages closely approximating to English prices. As regards the question of branch offices *versus* agents, there is no doubt about it that branch offices ought to be very much more efficient.

Mr. H. W. WILSON (Messrs. Miller, Wilson and Pegg) said that what struck him most about German works was the good discipline that prevailed, and the comparatively small amount of work turned out per man. He did not think that the German works could be producing very much more cheaply than works in this country, excepting on account of the fact that their output was very much larger. Where the German electrical manufacturing industry has its great advantage over this country is in its financial backing Personally, he thought that the only way for electrical firms in this country to make a profit was by a drastic reduction in their numbers.

Dr. F. H. BOWMAN attributed the superiority of the German industry to the better organisation of their foreign departments, their greater facilities in Banking, and the longer hours of work.

Mr. W. CRAMP (Municipal School of Technology, Manchester) thought that the high dividends paid by the German firms might indicate prosperity to the shareholders, but pointed to conditions unsatisfactory to those outside the combinations. It was said that it was difficult for us to export to Germany because of the tariff against machinery, and finished articles in general. Some few weeks ago he had visited the works of the Morgan Crucible Co., London, who make Morganite carbon brushes, and the manager had said that if it had not been for the foreign demand for these brushes they would have been obliged to give up making them. He mentioned that of the carbon brushes they turned out, one million per annum were going to Germany to the very firms mentioned in this Paper. On inquiring the reason why these firms placed their orders with the Morganite Co., he had been told that it was because the full technical data provided of every quality of brush were much appreciated, and uniform results could be relied upon; the English manufacturer was too slow to take advantage of this, and so continued to buy his brushes abroad.

Mr. J. W. THOMAS (The Electrical Co.) said that piecework was not in use for erection of machines, and pointed out that the high rate of interest paid only represented about 5 or 6 per cent. on the money if shares were bought to-day in the open market, so that the interest was not high, and it was really only the promoters who reaped large rewards. In addition to the leading companies mentioned, there were a large number of smaller firms who made special apparatus, and these firms were often ahead of the larger firms with novelties.

Mr. D. ADAMSON (D. Adamson & Co.) put down the difficulty of obtaining capital in England, not so much to the want of enterprise of English financiers, as to ignorance of the financiers of the possibilities of properly thought-out electrical schemes.

Mr. T. H. M. SWINBURNE (Altrincham) said that apart from all questions of financial backing and tariff, much of the success would seem due to the fact that, whenever a German firm wishes to compete in this country, it invariably employs English engineers to exploit its interests in the first instance, then, when a connection is established, the Englishmen are replaced by Germans, and the usual results follow.

Mr. S. J. WATSON (Borough Electrical Engineer, Bury) asked for some more information as to the industrial banks, and emphasised the importance of the German double-shift system.

Mr. A. R. STELLING, in reply, said that the keynote of the whole system of the trade abroad was organisation and the question of having proper staffs and competent agents. With regard to the question of shifts, in most places they worked two shifts, but there were some where they work in three shifts. With regard to the wages, the standard rate was lower there than it is in England, except for certain classes of female labour. These German firms did insist on their specifications. The author mentioned a case where one of these firms had been asked to tender to a specification. They ignored the specification at first, and tendered for what they thought suitable, and only altered the specification at the last moment to get the job. On the question of shifts, certainly double shifts do point to a somewhat good state of trade.

Electrical Engineer Volunteers.—The London Division of the Electrical Engineer Volunteers held their annual dinner at the Monico Restaurant, Piccadilly, on Saturday night. Col. R. E. B. Crompton, C.B., presided.

Arc Lamp Lowering Winch.—Among the novelties at the Physical Society's Exhibition last week was a new driving mechanism the essential feature of which is that all cog and worm wheels are avoided. The advantages claimed are high efficiency, compactness and safety, and low cost. This mechanism has already been applied by the London Electric Firm (Croydon) to arc lamp raising and lowering gear.

THE DUTIES OF THE INSTITUTION OF ELECTRICAL ENGINEERS TO THE ELECTRICAL INDUSTRY

WE have received a copy of the following letter addressed by Mr. E. Garcke to the Secretary of the Institution of Electrical Engineers, and dated December 10th, 1909:—

DEAR SIR,—I am sorry that at the Institution meeting last night the President disparaged the statement I made by describing it as "politics," and that he warned other speakers not to discuss the Paper before the meeting on the same lines. I maintain that it was impossible to express disagreement with the conclusions of the Paper without touching on matters which might be called politics. His ruling was equivalent to saying that disagreement must not be expressed with the conclusions suggested by the Paper.

Some statements were made by Mr. Mordey, Past President, which in the general interests of the industry should, I think, be further explained. I understood him to say that it was not the province of the Institution to undertake the protection of the industry in legislative and commercial matters. At the same time, in reply to my statement that the Institution had neglected to deal properly with the Electric Lighting Bill of this year, he said that a Special Committee had been appointed which had made representations to the Board of Trade on the subject, but that it was the duty of the Institution to look at these matters not from the point of view of the industry alone, or of any particular section of it, but also from the point of view of the consumers and the general interests of the community.

If this is the accepted view of the province of the Institution in regard to these matters, then I can readily understand that the Special Committee would allow the draft Audit Clause and the draft clauses dealing with competition between local authorities and companies in the Bill to pass, for inactivity would in that case be the best policy for the Institution.

But as representing very important and considerable interests in the industry, and I am aware that there are other and no doubt equally representative members who agree with me, I say unhesitatingly that in my opinion this view of the province of the Institution ought not to prevail with the Institution. Such exalted functions pertain to Legislative and Government Departments. As matters stand at present, a large proportion of electrical men are under the impression that the Institution recognises and undertakes the responsibility of safeguarding the interests of the electrical industry in the battle of life. We ought not to be left in any doubt upon the subject, and in my view the province of the Institution in legislative and industrial matters should be settled and definitely stated. So long as there is any doubt about the matter it is impossible to make other arrangements for the performance of these necessary duties. The position of the electrical industry in its legislative and industrial aspects is so unsatisfactory, and the attitude of the Institution in regard to these questions so uncertain that with due regard to the large interests involved such uncertainty ought not to continue, and I trust, as I stated last night, that the President and the Council will give the matter their early and serious consideration.

I am, dear sir, yours faithfully,
E. GARCKE.

To this the Secretary replied as follows:—

DEAR SIR,—I am instructed to inform you that your letter of December 10th was read to the Council at the meeting held yesterday, and that it will receive consideration.

I am, yours faithfully,
P. F. ROWELL,
Secretary.

Institution of Electrical Engineers,
92, Victoria Street, S.W.
Dec. 17th, 1909.

The Will of Mr. F. H. Medhurst.—Mr. F. H. Medhurst, who was found shot in a Croydon hotel on October 26th, left a will in which he made bequests amounting to £100,000. His estate, however, has been valued at only £3,038 gross, with net personalty *nil*. The executors named in the will have renounced probate, and his widow has renounced probate on behalf of the children. Letters of administration have been granted to Lord Armstrong, a creditor.

Imperial College of Science.—The Education Committee of the London County Council recommend a grant of £8,000 to the Imperial College of Science and Technology in respect of the financial year to August 31st, 1910, subject to 25 free places being reserved for the Council's scholars.

Lord Crewe, Chairman of the Governors, in distributing the diplomas, medals, and prizes to the successful students on Thursday, said that they represented a higher standard of work than had been the case in any previous year.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering."]

ALUMINIUM.—The British Aluminium Co., 109 Queen Victoria Street, have issued a conveniently arranged folder giving full particulars, resistance weights, &c., of standard aluminium conductors, ranging from 0·000924 sq. in. to 1·606 sq. in., side by side with the nearest equivalent sizes of copper conductors, showing clearly how the aluminium conductors are only about half the weight of copper conductors of equal conductivity.

ELECTRICAL LISTS, &c., FOR SOUTH AFRICA.—Among a batch of lists, &c., which are being issued by the A. E. G. Electrical Co., of South Africa, Ltd. (Caxton House, Westminster), are those dealing with the following:—Electricity applied to printing; continuous current interpole railway motors; lead-covered cable accessories; switchboard measuring instruments of the electro-magnetic and moving coil types; ceiling fans; automatic starters for three-phase motors, and metal flower lamp shades.

OVERHEAD TRAMWAY EQUIPMENT.—A new catalogue of overhead line material for tramways, including circular, grooved, and figure eight section trolley wire, ears, splicing tubes, hangers, pull-offs, line insulators, frogs, crossings, section insulators, trolley heads, and tools has been issued by British Insulated & Helsby Cables, Ltd. (Prescot). Some idea of its completeness, notwithstanding the fact that it is a second supplement to the firm's general catalogue relating to overhead equipment, may be gathered from the fact that no less than 114 different patterns of ears alone are illustrated.

HEATING AND COOKING APPARATUS.—A new list from The Electrical Co., Ltd. (123–4 Charing Cross Road, W.C.) contains particulars of a considerable range of electric heating and cooking appliances, including kettles, hot plates, water heaters, urns, curling-iron heaters (including special forms for theatre dressing-rooms, combined with heaters for paints), workshop heating tables for articles to be lacquered, drying plates, hair-drying apparatus, cigar lighters, soldering irons, and various accessories.

TANTALUM LAMPS.—Messrs. Siemens Brothers Dynamo Works, Ltd., Tyssen Street, Dalston, N.E., announce in a new price sheet some new sizes of tantalum lamps, including a 10 c.p. lamp 65 to 120 volts continuous current, and for 65 to 120 volts either alternating or continuous current. In addition to this they are also placing on the market a 16 c.p. lamp for 140 to 160 volt direct current circuits. Tantalum lamps are now made in voltages ranging from 20 to 240 volts for ordinary use. Tantalum candle lamps can also now be obtained in voltages from 20 to 60, in 5 or 10 c.p. at the price of 2s. each. These candle lamps are manufactured in exceptionally neat type of bulb, and should appeal to consumers who have installed candelabra fittings. Some slight alterations in the sizes of the standard bulbs have been made. The new list, which is in the form of a small folder, can be printed with the name of any contractor or agent.

REFLECTORS FOR TANTALUM LAMPS.—Another list from Messrs. Siemens Brothers' Dynamo Works gives particulars of a number of forms of reflector for shop window and show case lighting with concealed tantalum lamps.

ELECTRIC HEATING AND COOKING.—The latest edition of the catalogue of electric heating and cooking apparatus of the General Electric Co., 71 Queen Victoria Street, E.C., contains details of a large variety of appliances. The heaters listed include lamp radiators, convectors (or, as the Company prefer to call them, "elevectors,") and non-luminous heaters acting by conduction. Of all these classes there is a great variety of designs, including those for ships, trains, tramcars, etc., as well as for houses and business premises. The cooking appliances, on the "Archer" system, include kettles ranging in price from 2s. to ten guineas, saucepans and other domestic utensils, urns, coffee machines, hot-water jugs, shaving pots, hot plates for cooking in ordinary utensils and for keeping dishes warm, toasters, hot cupboards, ovens, and complete cooking outfits. Therol and other boilers, flat irons, soldering irons, and a variety of other miscellaneous application of electrical heating are also dealt with.

ARC LAMPS.—Another of the General Electric Co.'s new lists is that of "Angold" enclosed arc lamps, including the shuntless, differential and double arc patterns for continuous current with single and double enclosure, and also special alternating current enclosed lamps.

CONDUIT MATERIAL.—The General Electric Company are also issuing a revised catalogue of "Geekoduct" insulated conduit material and fittings. This system employs enamelled steel tubes with an insulated lining of impregnated papier-mâché. A very complete series of accessories is included.

FEED-WATER ECONOMISER.—A leaflet is to hand from Mr. G. Braulik (8 Lambeth Hill, E.C.), calling attention to the Düsseldorf counter-current circulation economiser, for which he is sole agent for the United Kingdom and British possessions abroad.

POLICE LAMP.—A special form of accumulator Police lamp is being introduced by Messrs. L. E. Wilson and Co., 20 Cross

Digitized by Google

Street, Manchester. The complete lamp measures 5½ in. by 2¾ in., and weighs 29 ozs. The case is fitted with a belt attachment, and there is a detachable bull's eye reflector together with a strong and convenient switch. The accumulator has a capacity of 4 ampere hours, and one charge will maintain a brilliant light for eight to ten hours. The glow lamp is of the metal filament type, and gives a brilliant white light.

FREQUENCY INDICATORS AND TACHOMETERS.—A new list from Messrs. Siemens Brothers & Co. (Caxton House, Westminster, S.W.) describes a number of applications of the Frahm Patent vibrating reed resonance instrument, both electromagnetically operated as a frequency indicator and also for attachment to high-speed machinery, for use as a tachometer by resonance with the mechanical vibration

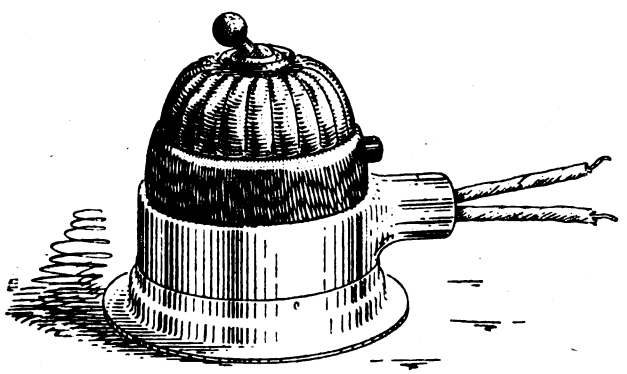
ARC LAMPS.—A new price list from Mr. G. Braulik (8 Lambeth Hill, London, E.C.) gives particulars of the "Eclipse" semi-enclosed long-burning arc lamp. This burns pure carbons arranged vertically and has a burning life of 30 hours on one trim. The arc voltage is 80 volts, so that the lamps can be run two in series on 200- or 220-volt circuits or singly on 100-volt circuits.

FEEDWATER METER.—A pamphlet from Messrs. Sanders, Rehders & Co., Ltd., contains a description of a new form of water meter specially suitable for measuring feed water. The apparatus has a positive action, controlled by the actual weight of the water in three compartments, which are successively filled and emptied.

CALENDARS, &c.—A wall calendar from Messrs. Hamilton Brothers (Glasgow) call attention to "W. H." ironclad electric control.

The Hart Accumulator Co. (Marshgate Lane, Stratford, E.), are distributing to their friends a useful and convenient office blotting pad.

The Western Electric Company, Norfolk House, Victoria Embankment, W.C., have sent us a desk calendar of artistic design.



Our Editor and Assistant Editor have been very pleased to receive copies of the 1910 edition of the well-known morocco leather covered pocket-book and diary issued annually conjointly by Siemens Brothers & Co., Ltd., and Siemens Brothers' Dynamo Works, Ltd. A new set of illustrations are included, which indicate the wide sphere of action of the two companies.

The General Electric Co. are sending to their friends a large handsome leather blotting-book, with copious and convenient pockets. Another instance of their thoughtfulness is a set of refills for their calendar of last Christmas, which still adorns one of our editorial office tables. Some handy blotting sheets are also being distributed by the General Electric Co., and bear a calendar for January and February, 1910, as well as a scale of inches and a reminder that Osram lamps save 70 per cent of current.

The pocket diary of Simplex Conduits this year has been carefully revised, and contains a mine of useful information in a most suitable form, as well as being a pocket book of well-thought-out arrangement.

A COMBINED TUMBLER SWITCH AND CIRCUIT BREAKER

An automatic tumbler switch, which is claimed to be the smallest circuit breaker in the world, has been designed and patented by Mr. C. W. Denny, of 2 Pembroke Cottages, Edwardes Square, Kensington, W. We are able to illustrate in the accompanying figures an automatic switch and wall-box combined, suitable for conduit wiring systems. The switch, which is a slight modification of the standard 5 amp. tumbler

Denny Automatic Tumbler Switch.

switch, is mounted directly on top of a small pot magnet, the winding of which is in series with the switch. The magnet is supplied with a circular keeper or armature, which in turn operates a rocking lever in the switch. Projecting through the porcelain switch base is a push-button, which also engages with the said rocking lever. In closing the switch, the operating lever or knob is pulled down in the ordinary manner; this pushes the contact blade home. The operating knob then returns to the "off," or starting, position. The contact blades are retained in position by a small catch attached to the extreme end of the rocking lever. Should it be desirable to open the switch by hand, the push-button is pressed, and the rocking lever tilted, and the switch blades released. On the other hand, should the current passing through the switch exceed a predetermined value, the armature is attracted towards the magnet, and the rocking lever is again operated, and the switch blades released.

The object of this switch is to eliminate as far as possible the use of fuses on lighting and small power circuits, and it can be used either for controlling lights from a distribution-board or from separate points. In the case of the former, the distribution board is either fitted with D.P. automatic tumbler switches, or with S.P. automatic tumbler switches and S.P. fuses, the fuse being, of course, rated about 50 per cent. above the load at which the switches are set to operate; in either case the size and consequent cost of the distribution board is considerably reduced. If the switches are used at various points of a building, a small distribution board is used containing S.P. automatic switches or fuses as the case may be.

CONDUIT EXPLOSIONS IN THE CITY

About mid-day on Wednesday of last week, a series of three gas explosions, primarily caused by a leakage from a gas pipe under the road, occurred in man-holes and cable-boxes at the Blackfriars end of Queen Victoria Street. Five men were injured, and as the traffic down Queen Victoria Street had to be suspended, that in Fleet Street, Ludgate Hill, and Cannon Street was very congested for some hours.

The first explosion took place in an electric light cable inspection box, situated under the railway arch, but this only resulted in the breakage of the box cover. Previous to this explosion, two employees of the General Post Office had lifted the cover of an adjacent manhole, which gives access to a new 90 duct cable conduit 20 feet below the street level, and passing under the new passenger subway. (See Electrical Engineering, Sept. 16th, 1909, page 810, where on a plan of the subways and cable ways, this manhole is indicated as *B*.) They noticed a smell of gas, and after waiting a time to allow the gas to escape, one of them, Breeton, prepared to descend into the manhole. The afore-mentioned explosion in the adjacent inspection box then occurred, and was immediately followed by an explosion of gas in the G.P.O. manhole. The man Breeton was badly burned, and was taken to a hospital. The actual cause of the ignition of the gas in either of the above cases has not yet been discovered. A lighted match or cigarette-end may have been responsible, and with regard to the second explosion, it is possible that the G.P.O. workmen's candles were the cause, though ignition by a match or as a result of the immediately preceding explosion are equally feasible.

The third explosion took place nearly half an hour after the first two, in two cable boxes not far distant from the G.P.O. manhole. These boxes afford means for the inspection of some cables belonging to the Charing Cross, West End, & City Electricity Supply Co. We understand that this company's officials had already detected the presence of gas near these boxes in the early morning, and had telephoned the Gas Co., who had asked them to lift the box covers in order to allow the gas to escape. It was while this was being done that the third explosion occurred. The police had not at that time cleared the whole space, and passers-by, many certainly smoking, were watching the Charing Cross Co.'s men lifting the covers. The escaping gas was in some way ignited, and not only were three of the men badly burned, but one of the covers fell on a passer-by, seriously injuring him in the leg.

The whole of the traffic over this part of the street was stopped, and the space cleared by the police to prevent further accidents. In the meantime a gang of navvies were set to work by the officials of the Gas, Light & Coke Co., and just before six in the evening the leak was discovered in a pipe just outside the Hand-in-Hand Insurance Co.'s offices. It is not easy to explain how the gas got into the cable boxes and manholes, but it must have percolated through the surrounding soil, and the brickwork and cement linings. No appreciable damage was done to cables.

Telephones in Turkey.—The *Times* Constantinople correspondent states that the Special Committee appointed by the Turkish Minister of Finance has completed with Mr. H. Laws Webb the draft agreement and specification governing the future telephone service of Constantinople. The documents have been approved by the Minister of Finance, and will now be translated into Turkish, and submitted to the Council of Ministers for signature after the holidays. As we have already announced, the work of installing a telephone system in Constantinople is to be undertaken by a syndicate composed of the National Telephone Co., Ltd., British Insulated and Helsby Cable, Ltd., Western Electric Co. of Chicago, and the French Thomson-Houston Co., Ltd.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 16th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications. Names in italics indicate communicators of inventions from abroad.

17,349/08. **Oscillation Generator for Wireless Telegraphy.** E. VON LEPEL (Charlottenberg). The discharger consists of two metal discs or cylinders separated by a thin sheet of paper. The paper covers the greater part of the surface at first, but is gradually eaten away by the discharge which then spreads over a large surface. This discharger is placed in parallel with one or more oscillation circuits, and can be supplied from either an A.-C. or a D.-C. source. Two claims, three figures.

17,619/08. **Metal Filaments.** C. T. FULLER (Schenectady). The yellow trioxide of tungsten is mixed with an aqueous binding agent containing 25 per cent. corn-starch. Filaments squirted from the mixture are reduced in an electrically-heated graphite tube with a protective covering of coke. The carbon boats containing the filaments are lined and covered with rutile (TiO_2), or powdered tungsten, either of which protects the filaments from carbon vapour without sticking to them, while it allows the carbon monoxide to escape. A stream of hydrogen is maintained through the tube. Three claims, two figures.

16/09. **Brush Gear.** J. TAYLOR (Mather & Platt, Ltd.) The metal spindles for carrying the brush-holders are tubular, and are expanded into holes in the rocker arm. A sleeve and a washer of insulating material insulate the spindle from the rocker. The eyes of the cross-connectors between like brushes are passed over the spindles, which make firm contact when expanded. As an alternative, the socket in the rocker casting and the eye of the connector can be shrunk on to a solid spindle. Four claims, two figures.

1,086/09. **Lift Control.** J. G. CHILDS and T. S. HILL (J. G. Childs & Co.). In a push-button lift-control system, a pivoted switch controlled by two solenoids is provided for each floor. One solenoid closes the switch and keeps it closed after the corresponding push-button has been momentarily depressed, while the other solenoid of each switch is included in a circuit which is completed on the depression of any push, and serves to hold open the switches whose closing solenoids have not been energised. When one push has been depressed, all the other pushes are thus rendered inoperative until the car has completed its journey. Four claims, four figures.

2,389/09. **Apparatus for treating Metal Filaments.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). The squirted filaments are attached to clamps on an endless band which passes through a long chamber supplied with the treating gases. Current is supplied through brushes and contact rails, and caused to increase gradually and automatically as the filaments pass along into the end at which the pure gases are led in. Four claims, six figures.

8,146/09. **Metal Filaments.** R. HOPFELT (Berlin). The squirted filaments are brought to incandescence in an atmosphere of a halogen compound such as arsenic tri-chloride or phosphorus tri-chloride. This not only sinters the filaments, but removes all hydrocarbons. Carbon filaments can be treated in the same way at a lower temperature. Two claims.

14,505/09. **Flame Arc Lamp.** SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke Ges.*). One carbon rests on a support which enters a longitudinal slot in the carbon at the red-hot portion near the arc. The slot contains a paste of potassium or sodium silicate and carbon, with or without light-producing salts, which softens and crumbles away at about 600° C. and allows the carbons to feed down. Three claims.

Opposition to Grant of Patents

27,470/08. **Loading Coils for Telephone Cables.** W. S. SMITH and W. P. GRANVILLE. This patent has been granted in spite of the opposition entered by Messrs. Siemens Bros. & Co. Full particulars will be found on another page of this issue.

2,216/09. **Production of Long Arcs.** CENTRALSTELLE FÜR WISSENSCHAFTLICH-TECHNISCHE UNTERSUCHUNGEN GES. The grant of this patent, which relates to the production of long arcs such as those used in the fixation of atmospheric nitrogen, has been allowed in spite of opposition.

Patent Amended

8,263/09. **Fuses.** SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens & Halske Akt.-Ges.*). A disclaiming note has been added to this specification, and the drawings amended, as a result of the extended investigation under Section 8 of the Patents Act. The patent covers fuse sockets, plug caps, and cartridge fuses with gauge-pieces having different internal diameters, and contact studs of different lengths. The different diameters prevent interchangeability with respect to current and the different stud-lengths with respect to voltage.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: WUNDERLICH and HUGHES [Lowering gear] 14,972/09.

Dynamos, Motors, and Transformers: BESTETTI and SPINELLI [Single-phase induction motor] 18,531/08; LANCASHIRE DYNAMO & MOTOR CO., WOOD and MCLEOD [A.-C. machines] 26,198/08; LEITNER [Dynamo driving mechanism] 27,149/08; BRITISH THOMSON HOUSTON CO. (*Allgemeine Elektricitäts Ges.*) [A.-C. machines] 786/09.

Electrometallurgy and Electrochemistry: SMITH and DEAKIN [Electroplating apparatus] 27,624/08.

Heating and Cooking: HEARN, 25,485/08.

Incandescent Lamps: SIEMENS & HALSKE AKT.-GES. [Production of tantalum] 22,873/08.

Storage Batteries: BILARD [Plate supports] 28,075/08.

Switchgear, Fuses, and Fittings: LAKE [Lamp-shade holder] 25,587/08; THORPE and THORPE METER SYNDICATE [Electrolytic devices for circuit-breakers] 25,763/08; WEST [Fuses] 26,251/08, and [Resistance grids] 26,252/08; WANDREY [Shutter indicators] 26,502/08; WEATHERILL [Insulators] 27,635/08; CURTIS, MACKLEY and ADAMS MANUFACTURING CO. [Solenoid-controlled switches] 2,217/09; IFFLAND [Controller for hammers, cranes, lifts, &c.] 3,180/09; HANSEN [Automatic circuit-breaker] 8,105/09; MYGATT [Lamp shades] 8,539/09.

Telephony and Telegraphy: VON LEPEL [Oscillation generator] 26,363/08; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Neutralising inductive disturbances due to traction systems] 466/09; OLIVER [Telephonic apparatus] 12,857/09; SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*) [Telephone exchange switch-plugs] 18,326/09; SIEMENS BROS. & CO., and GRIMSTON [Telegraphic apparatus] 19,603/09; SIEMENS & HALSKE AKT.-GES. [Automatic telephone exchanges] 21,978/09.

Traction: PREW [Speed limiter] 26,083/08; GRESHAM [Air brakes] 26,362/08.

Miscellaneous: COLLIER [Burglar alarm] 25,525/08; VENNER [Signs] 26,331/08; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Silicon alloys] 26,826/08; KIRCHHOFER [Self-winding clocks] 5,883/09; WATERMAN [Electrically operated valves] 8,315/09; SCHOOP [Welding aluminium] 8,778/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Dynamos, &c.: FELTEN & GUILLEAUME LAHMEYERWERKE AKT.-GES. [Converters] 25,263/09; SOC. JOST ET CIE. [Balancers] 26,600/09.

Electrometallurgy, &c.: BUNET and BADIN [Arc furnace for combining oxygen and nitrogen] 16,225/09; ASKENASY [Production of aluminium] 23,315/09.

Switchgear, &c.: MURRAY [Cut-outs] 23,229/09.

Traction: BOWLES [Brakes] 25,113/09; GROB [Vehicle lighting] 27,937/09; PIEPER [Control of vehicles] 28,082/09.

Miscellaneous: FELTEN & GUILLEAUME LAHMEYER WERKE [Electric reversing gear] 9,338/09; BADOIS [Electric frictional devices] 27,370/09.

Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

24,702 of Dec. 24th, 1895. **Railway Signalling.** WESTINGHOUSE BRAKE CO., LTD. (*J. P. Coleman, U.S.A.*). In an electric signal and point shifting system, the position of the operating lever corresponds with that of the point, and when the lever has been moved and the rails shifted, the movement must be completed before the lever can be returned to its original position. Both positions of the point are positively indicated.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, &c.: G. S. ELLIS and A. M. TAYLOR, 17,814/05.

Dynamos, &c.: BRITISH THOMSON-HOUSTON CO. (*A. D. Lunt, U.S.A.*) [Phase and frequency changers] 15,378/00; H. H. LAKE (*General Electric Co., U.S.A.*) [Transformer] 18,926/02.

Storage Batteries: A. LEHMANN and A. MANN [Plates] 20,145/97; H. N. WARREN, G. BUSSCHOTS, and J. M. WOOD [Prevention of sulphating] 17,674/05.

Traction: N. GREENWOOD and J. HIRD [Track brakes] 17,693/01; A. R. L. WILLIE [Clock to register time motors are working] 18,953/03.

Miscellaneous: T. MCKENNA (*Electric Selector and Signal Co., U.S.A.*) [Electromagnets] 19,303/96; MARCONI'S WIRELESS TELEGRAPH CO and E. PRIDDLE [Induction coil contacts] 19,015/03; H. H. LAKE (*Soc. Anon. Matthey & Co.*) [Insulating composition] 18,920/04.

Digitized by Google

INTERCONNECTION OF ENGINEERING SOCIETIES

To the Editor of Electrical Engineering.

Dear Sir,—Engineering in its progress has been divided into numerous branches which, as time passes, become more and more defined and distinct. In consequence, there has appeared from time to time the necessity of forming new societies in order to give adequate attention to the details of the respective branches. The founders of new societies are naturally inspired in their work by the opinion that their objects cannot be obtained from any existing society. There is, however, a great danger that, in their enthusiasm, they may overlook the fact that some other societies have similar objects, and that they might strengthen their cause by recognising the value of the sympathy and influence of such societies. All technical engineering societies have at least one object in common, *i.e.*, "To direct the great sources of power in Nature for the use and convenience of man," and this ideal should of itself be sufficient to ensure a common interest and harmony. There is also a danger of misunderstanding arising between new and existing societies. A dignified interest on one part might, on account of insufficient opportunity for discussion and explanations, be mistaken for an unwarranted intrusion or interference.

The engineering industry is a busy one, and has, as a rule, very little time to spare for the discussion of social questions. Individuals leave such affairs alone probably under the impression that somebody else will attend to them. Would it not, therefore, be a good policy for one of the existing great institutions to form a small advisory board whose privilege it would be to confer with other bodies and to form, as it were, an "Interconnector" between them? It would be formed of experienced men with a knowledge of the objects of all existing societies and institutions and, having authority to approach founders of any new movement and interesting themselves in the objects, much could be done to prevent clashing of interests and thereby advance the science of engineering. The Institution of Civil Engineers embraces all branches of engineering in one powerful society, and are, therefore, in the best position to form a board to act as mediators.

Those who have attended meetings of the new society which is at present called "The Institution of Mining Electrical Engineers," will recognise that the writer has them in mind in making the above suggestion. To those who were not present, it is sufficient to say that a diversity of opinion existed on a suggestion to modify the title into "Electrical Mining Society," or some other title which would be less likely to be confused with the title of the parent Institution of Electrical Engineers. The objects of the new society have been clearly defined and explained in the technical press, and it is plain that they are not entirely covered by other mining institutions or by the Institution of Electrical Engineers. They aim at the education and advancement of the engineer in charge of electrical plant in mines, and also the education of manufacturers, mining engineers, and managers, in matters relating to electrical requirements, specifically for mines. Whilst many individuals thus effected are engineers who are members of the existing technical societies, there are others who by reason of previous training, would not be eligible for election into the established institutions. But as it is one of the primary objects of the new society to induce men to qualify as capable electrical engineers for mines by study and examination, there is every reason to expect that it will eventually be a training ground for the older institutions.

It is suggested that an Advisory Board to act as an interconnection between engineering technical societies, could at the present time do much good service, and the movement in connection with electricity in mines is a case in point requiring immediate consideration.

Yours faithfully,
H. W. C.

LOCAL NOTES

ARGENTINE: *Buenos Aires: Tube Railways.—The Review of the River Plate* states that the contract between the City of Buenos Aires and the Anglo-Argentine Tramway Co. for the construction of tube railways has been signed. The concession is for 80 years, during which time the Corporation will receive 6 per cent. of the gross receipts. At the end of the concession all the Company's property, including their tramways, will revert to the Corporation without charge.

BISHOPS STORTFORD: *Electricity Supply.*—The Council's consulting engineers, Messrs. May & Hawes, have presented a report upon an electricity scheme for the district. It is proposed to instal two Diesel oil engines and dynamos, each of 75 kw. capacity. The estimated cost, including buildings (but not land), electrical machinery, oil storage tanks, pipes, switchgear, and cable connections, battery, reversible boosters, feeder and distributor cables, house service meters, and 104 public lamps (metal filament) amounts to £12,750. An output of 100,000 units per annum is estimated, the total revenue being £2,048. The working expenses are put at £1,020, and after meeting interest and repayment charges at 7·2 per cent., a net profit is shown of £110. It is pointed out, however, that this result is not likely to be attained in the early stages of the undertaking, and that the first two years are likely to involve a deficit.

BRITISH HONDURAS: *Import Tariffs.*—The Board of Trade are in receipt of a copy of an Ordinance, the effect of which is to remove from the list of articles accorded free entry into British Honduras certain specified fittings for electric lighting, viz., shades, electroliers, standards, and pendants.

BUENOS AIRES: *Telephone Tax.*—The *Review of the River Plate* states that the proposal to place a tax of one dollar per month on every telephone instrument installed in the Province is being protested against by the telephone companies.

BURSLEM: *Electricity for Power Purposes.*—Mr. Ashton Bremner, the Borough Electrical Engineer, is delivering a series of lectures at the Woodward Institute upon the advantages of electricity for power purposes. The object of the lectures is to stimulate the interest of local manufacturers, and especially to demonstrate the advantages of electricity in relation to the potting trade. Mr. Bremner points out that far too few of those interested in the staple industry of the district understand the advantages which electricity offers them.

CANADA: *New Electric Power Company.*—An application will be made to the Canadian Parliament at its next session for an Act incorporating a company, under the name of the St. Lawrence Power Transmission Co., Ltd., with a capital of £50,000. The company is to have the right to generate and distribute electrical energy, &c. The head office of the company is to be at Cornwall, Ontario.

Electric Traction.—Application has been made at Ottawa for the incorporation of a company for the purpose of constructing an electric railway from Port Hope to Toronto, passing through Newcastle, Bowmanville, Oshawa, and Whitby, with branches to Uxbridge, Lindsay, and Peterborough, and also branch lines south to Lake Ontario. The capital is £200,000.

CARDIFF: *Maintenance of Tramway Track.*—The City Treasurer has presented a report on the question of providing for depreciation in connection with the tramways undertaking. He first of all points out that whereas the average cost per mile of single track for 67 other undertakings is £12,583, in Cardiff it is no less than £24,138. The present tramways depreciation fund is £19,004, and there is also a reserve fund of £9,952. The City Engineer estimates that by 1917 the sum of £89,320 will have to be expended upon track renewals, and in order to obtain this the sum of £6,604 10s. must be set aside annually during the next eight years, and be added to the two sums already in hand.

CROYDON: *Tramway Traffic.*—It is stated that in the 15 weeks from August 6th to November 19th, following the through running of tramcars between the London County Council and the Corporation systems, 998,000 more passengers were carried than in the corresponding period of last year. The effect of the through running has been to cause the motor omnibuses to be taken off the streets.

DEVONPORT: *Corporation and Tramways Co.*—The Devonport & District Tramways Co. have notified the Corporation of their intention to run cars on the leased lines again. The overhead equipment has been repaired and everything is ready, the local manager only waiting final instructions to start the cars. At the last meeting of the Corporation the Town Clerk stated that the company had to run trams according to what the Corporation considered to be a reasonable service, but there was an appeal to the Board of Trade on either side. It will be remembered that legal proceedings were recently taken by the Corporation against the company for having ceased to run cars over the leased lines. The company, as we have already noticed, has deposited a Bill for next session of Parliament, in which there are several provisions relating to the dispute.

DUBLIN: *Gas v. Electricity.*—The Guardians of the South Dublin Union, being unable to come to any conclusion as to the respective merits of two schemes for electric and gas lighting for their buildings, have passed a resolution asking the Local Government Board to hold an inquiry to decide the question for them.

DUNFERMLINE: *Tramway Extension.*—The Fifeshire County Council recommend the local Council to oppose the applications of the Dunfermline & District Tramways Co. and the Wemyss & District Tramways Co. for powers to construct tramways in the district.

DUNOON: *Electric Lighting.*—The Board of Trade has

Digitized by Google

granted the Council an extension of time of twelve months in which to carry out their Electric Lighting Order.

HASTINGS: *Electric Wiring.*—After some discussion the Council have decided to insert the words "through a contractor, but not otherwise" in the clause in their Bill asking for powers to undertake the electric wiring and fitting of consumers' premises. The Electrical Contractors' Association threatened to oppose the Bill unless this were done, but the Electricity and Parliamentary Committees had declined to adopt the suggestion.

LONDON: *London County Council: The G.B. System.*—The Highways Committee have reported with regard to the expenditure upon the adaptation of the Aldgate-Bow tramways for the underground conduit and overhead systems, which would not have had to be incurred had this route been reconstructed in this manner originally instead of on the G.B. surface system. The Committee state they are advised that the expenditure in question amounts to £25,265. The Finance Committee propose that this sum should be charged against the general reserve fund. This was agreed to at the meeting of the Council on Tuesday.

Tramways.—The income tax payable in respect of the tramways has been fixed at £16,329 for 1908-9, against £10,567 for 1907-8.

Hackney: Electric Heating.—In order to push the use of electricity for domestic purposes, Mr. L. L. Robinson, the Borough Electrical Engineer, has offered to send out a radiator, an electric kettle, or an iron on approval for fourteen days.

Marylebone: Electricity Supply Charges.—The Electricity Committee have decided that current be supplied for the purpose of ice-making and freezing at 1d. per unit without any kw. charge.

St. Pancras: Electricity Finances.—The L.C.C. have drawn the attention of the Council to the fact that the whole of the surplus on the electricity undertaking in 1908-9 was transferred to the relief of the rates. The Borough Council is asked when considering the disposition of any further surplus from the electricity account, to bear in mind the large amount of loans which have been borrowed, mostly for 42 years, a period much in excess of the life of mains, machinery, and house services, and that 70 per cent. of the loans are on the annuity system of repayment, whereby the burden of repayment is heavier in the later years of the loan period than in the case of the instalment system.

LOWESTOFT: *Electric Tramways.*—The Lighting Committee have agreed to a reduction in the charge for tramways energy to 1¾d. per unit. The accounts of the tramways undertaking for the year ended September 30th show a deficit of £2,686. Of this sum £1,200 have been included in the current rate. The traffic receipts showed a decrease of £1,069.

Electric Lighting Accounts.—The accounts for the year to September 30th show a net profit of £176, after meeting capital charges, and, in spite of the effect of metal filament lamps, the revenue account shows an increase of £630.

MEXICO: *Electric Power Transmission.*—The *Mexican Herald* states that the Chapala Hydro-Electric and Irrigation Company, headed by Messrs. Fernando Pimentel and Fagoaga, of Mexico City, will shortly carry out a scheme for the transmission of electrical power to the Aguascalientes district from the Santiago river. The company will probably instal a large power plant at Las Juntas, and construct a canal from the Juanacatlan falls to that place, a distance of 26 kilometres (about 16 miles). At Las Juntas the fall of water would be sufficient for the generation of 90,000 h.p.

MIDDLESBROUGH: *Lapse of Tramway Powers.*—At the last meeting of the Corporation attention was drawn to the fact that the powers of the Middlesbrough, Stockton & Thornaby Tramways Co. for the construction of tramways in Southbank, Eston, and Grangetown had expired. The Company's Act for these tramways received royal assent in August, 1904, and they were given five years in which to complete the work.

MIDDLESEX: *Tramway Accounts.*—At the meeting of the County Council on December 16th, the Tramways Committee submitted their annual report to December 31st, 908. The total length of lines authorised is 43 miles, of which up to March 31st last 30 miles have been constructed and opened for public traffic. The lessees, the Metropolitan Electric Tramways, Ltd., expended £42,506, the chief items of which were: Cables, £15,778; rolling stock, £15,778; overhead equipment, £5,491; and buildings, £2,730. The traffic receipts were £304,747, or 11·497d. per car mile, the figures for the preceding year being £244,445 and 11·828d. The working expenses were £190,601, or 7·191d., per car mile against £146,450 and 7·087d. The car mileage run was 6,361,253, against 5,037,204, the passengers carried being 57,369,307 and 48,242,404 respectively.

RUNCORN: *Electric Lighting.*—The Runcorn Rural District Council have approved of the application by the Salt Union for an Electric Lighting Provisional Order for this district.

SOUTH AFRICA: *Victoria Falls Power Co.*—According to the *African World*, the Victoria Falls Power Co. have erected new buildings alongside the old Brakpan power station of the Rand Central Electric Co., the new power-house, consisting of eight B. & W. marine type boilers, and two 3,000-kw. A.E.G. turbo-alternators generating three-phase current at 10,600 volts, the frequency being 50 cycles per second. At the Simmerpan station of the company, there are 16 boilers, and four 3,000-kw. three-phase turbo-alternators. Provision is now being made for the installation of an additional 6,000-kw. of plant.

SPEN VALLEY: *Tramways.*—The British Electric Traction Co. are again applying to the Board of Trade for permission to abandon certain tramways authorised but not yet constructed. The powers in question relate to a tramway from Cleckheaton to Liversedge, and the Cleckheaton Council are asking the Board of Trade not to accede to the company's request.

SWINDON: *Hire Purchase Wiring.*—A scheme for the wiring of premises has been adopted under which the consumer is asked to enter into an agreement to pay a slightly higher price per unit. The scheme is only to be put into operation where the cost of the wiring will not exceed £10, and where the occupier of the premises is the owner.

WEST HAM: *Supply in North Woolwich.*—In October last the Council wrote to the Woolwich Council asking for facilities to supply current in bulk to the Port of London Authority. Woolwich Council has now replied to the effect that they hope to be in a position to give a supply to the North Woolwich area in the near future, and for this reason they are not prepared at present to favourably consider West Ham's request. The Town Clerk of West Ham is to apply to the Board of Trade under these circumstances for their consent to give the supply in question to the Port of London Authority under the provisions of the Electric Lighting Acts (Amendment) Act, 1909.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA.—The Melbourne City Council require an electrically-driven pump. Particulars from Messrs. McIlwraith, McEacharn & Co., Ltd., Billiter Square Buildings, London, E.C., and tenders by February 2nd.

DUBLIN.—Negotiations with the Corporation for a supply of electrical energy to the Abbey Sanatorium having fallen through, a scheme for the lighting of the building is to be drawn up by Messrs. Young & Mackenzie at an estimated cost of £4,405.

DUNDEE.—The Electricity Committee recommend that electric mains should be laid in Downfield at an estimated cost of £3,000.

ERITH.—The Electricity Committee require a high-tension three-phase A.-C. switchboard. Particulars from the electrical engineer, and tenders to the Town Clerk by January 10th.

HASTINGS.—An expenditure of £1,000 is contemplated upon mains extensions.

JAPAN.—The German Consul at Kobe states that the Kobe-Akashi Electric Railway Company, with a nominal capital of about £210,000, intend to build an electric railway from Kobe via Suma to Akashi, a distance of 11½ miles. The first section of 5½ miles is to have a double track, the rest of the line a single track. The Minomo-Arima Electric Railway Company propose to build an electric railway, 15½ miles in length, from Osaka via Ikeda to Takaradzuka, with a branch 2½ miles long to Minomo. The cost of the work is estimated at about £300,000.

LONDON: *Battersea.*—Application is to be made to the L.C.C. for sanction to a loan of £4,500 for the electricity undertaking.

Bermondsey.—Application is to be made to the London County Council for a loan of £2,120 for feeders, £2,000 for mains and services, and £500 for meters.

NEWCASTLE (Co. Down).—At the meeting of the Council last week, it was resolved to employ Mr. A. E. Porte, to report upon a scheme for lighting the town by electricity.

RHYL.—The Council are to apply for the loan of a further £1,000 in connection with the remodelling of their electricity undertaking. This is made up as follows:—Excess expenditure, £150; meters, £150; services, £250; and mains, £450.

SOUTH AMERICA.—The Mendoza Legislature has granted a concession to the Compañia Alemana Transatlantica de Electricidad to utilise the waters of the River Mendoza for the generation of electrical energy, and also to construct electric tramways in the City of Mendoza. Current will be generated at 30,000 volts.

SURBITON.—The Local Government Board has sanctioned a loan of £2,191 for additional electrical machinery.

TORQUAY.—A committee is to consider a proposed extension of the electric supply mains to Chelston, with a distributing station at Walnut Road. The estimated cost is £1,312.

WHITCHURCH.—The Town Clerk has been instructed to inquire whether any company will be willing to undertake the electric lighting of the borough.

Digitized by Google

Miscellaneous

AUSTRALIA.—Tenders are invited by February 23rd, 1910, for the supply, delivery, and erection at the Telephone Exchange, General Post Office, Sydney, of two junction line sections of common battery switchboard, in accordance with Schedule N.S.W. E.E. 63/09. Preference will be given to tenders complying most closely with the Department's requirements for prompt delivery. Preliminary deposits may be paid at the Commonwealth Offices in London, 72 Victoria Street, S.W.

AYR.—A proposal to extend the use of electric lighting in the streets was opposed at the last meeting of the Council, but the recommendations of the Lighting Committee were adopted.

The Tramways Manager recommends the fixing of time meters to 19 cars at an estimated cost of £40.

BRITISH COLUMBIA.—It is stated that the British Columbia Electric Railway Co. propose to construct additional tramways to the north, west, and east of British Columbia.

CANADA.—Arrangements are being made for the adoption of flame arc lamps and metal filament lamps for street lighting in those districts taking electric power from the Ontario special power commission.

CARNARVON.—The proposal of the National Electric Construction Co., referred to in our last issue, that street electric lighting should be adopted, has been referred to the Highways Committee, with instructions to secure expert opinion. The company propose to instal eight flame arc lamps, and the estimated annual cost with 1,200 burning hours per year, is put at £150.

COLWYN BAY.—The Light Railway Commissioners held an inquiry on Saturday into an application for the extension of the light railway to the Queen's Hotel, Old Colwyn. There is a dispute between the Council and the company owning the existing lines as to the conditions upon which the extensions are to be constructed, and consequently the Commissioners decided to grant the extension on condition that the company acquire sufficient roadway to widen the road to 24 ft., and to add a 6-ft. pathway where none exists at present. The company were not to be compelled to buy any property.

CROYDON.—It is proposed to spend £1,150 out of revenue for sinking a well at the electricity works.

DONCASTER.—The Doncaster Rural District Council have approved of two schemes of sewerage and sewage disposal for the rapidly increasing parishes of Adwick-le-Street, Owston, and Skellow, in which electrically driven centrifugal pumps will be used. The consulting engineers are Messrs. D. Balfour & Son, of Newcastle-on-Tyne and London.

EAST HAM.—£926 is to be spent in alterations to 15 cars, so that they may be used on the through route to Aldgate.

HANDSWORTH.—The Electricity Committee recommend the Council to undertake the hiring and hire-purchase of electrical apparatus.

ITALY.—The State Railways Department invite tenders for the supply of 50,000 metal filament lamps by January 26th, 1910.

LONDON: *London County Council.*—The Highways Committee recommend a further expenditure of £30,000 for the purchase of rails for the tramway undertaking.

Additional capital expenditure, amounting to £11,500, is recommended by the Highways Committee upon the reconstruction of the tramways from Hackney Road to Stamford Hill.

Marylebone.—With reference to the announcement in our Local Notes that special terms are offered for energy for ice-making plant, Mr. A. Hugh Seabrook, manager of the electricity undertaking, is desirous of hearing from manufacturers of such plant as to co-operative action in introducing it to consumers.

SWITZERLAND.—A concession has been granted to Messrs. Hunger, Braun, Wolf, Hitz and Durrer for the construction and working of an electric funicular railway from Coire to Mittenberg. The concession is for 80 years, and the line must be constructed within two years.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

S.E.—Gymnasium and extensions at Residential and Day Training College, Avery Hill, Woolwich, S.E. Architect, T. J. Bailey, L.C.C., Education Committee, Victoria Embankment, E.C.

N.W.—Proposed Court House, Hendon, N.W. Surveyor, H. T. Wakelam, Middlesex County Council, Guildhall, Westminster, S.W.

New buildings for Works Department, Marylebone. Surveyor, J. P. Waddington, Marylebone Borough Council.

W.—Additions and alterations to 16 Grosvenor Street (£7,000). Architect, F. W. Foster, 26 Bedford Row, W.C.

Conversion, Grosvenor Restaurant into cinematograph hall, Pimlico, S.W. Architect, W. G. R. Sprague, 10 Jermyn Street, W.

S.W.—Additions and alterations to 36 Belgrave Square (£5,000). Architect, F. W. Foster, 26 Bedford Row, W.C. Builders, Allen and Co.

School, Kensington (£25,300). Architect, T. J. Bailey, L.C.C., Education Committee

New buildings, Middlesex Hospital. Architect, E. T. Hall, 53 Bedford Square, W.C.

School, Shepherd's Bush (£18,000). Architect, T. J. Bailey, L.C.C., Education Committee.

School, Adelaide Road, Hammersmith (£24,000). Architect, T. J. Bailey, L.C.C., Education Committee.

E.C.—Insurance offices, Finsbury Square, E.C. Architects, Gilbert and Constanduros, 41 Finsbury Square, E.C.

PROVINCES.

ABERDEEN.—Theatre. H. C. Cavanagh, managing director Aberdeen.

AYR.—Restaurant, Alloway Street (£5,000). B. Houston, Ayr, N.B.

BUXTON.—Cottage Hospital. The Governors, New Cottage Hospital, Buxton.

CARDIFF.—Buildings for Y.M.C.A. (£3,800). Architects, Speir & Beavan, Borough Chambers, Wharton Street, Cardiff.

ECCLES.—Tenders are invited for the electric wiring of the Beech Street Council School. Particulars from Mr. Henry Lord, 42 Deansgate, Manchester, and tenders to the Town Clerk by December 31st.

HULL.—School, Sidmouth Street (£17,500). City Architect, J. H. Hurst, Town Hall, Hull.

MIDDLESBROUGH.—Library, Dunning Street (£11,600). Architects, Russell & Cooper, 11 Gray's Inn Square, W.C.

SWANSEA.—New school, Pleasant Street (£2,000). The Trustees.

TENDERS RECEIVED AND ACCEPTED

EDMONTON.—The Guardians have accepted the tender of the Edison & Swan United Electric Light Co., Ltd., at £574 13s., for cables and switchboard, this being the lowest British tender. The Guardians decided to give the preference to British cables, although an extra expenditure of about 10 per cent. is involved compared with foreign tenders.

HINDHEAD.—The following tenders have been received by the Hindhead and District Electric Supply Co. for cables, feeder pillars, &c., for the high-tension extension. The second figure includes oil-break switches:—Callender's Cable & Construction Co., Ltd., £4,884 13s. and £4,958 13s.; British Insulated & Helsby Cable Co., Ltd., £4,776 5s. and £4,805 5s.; Henley's Telegraph Works Co., Ltd., £4,752 13s. and £4,807 13s.; Siemens Bros. & Co., Ltd. (accepted), £4,669 9s. 10d. and £4,733 5s. 10d.

The tender of Messrs. Mirrlees, Bickerton & Day, for a Diesel-E.C.C. generating set, including motor alternator, switchgear, cables, and connections, has been accepted at £2,475.

LONDON: *London County Council.*—Orders for electrical fittings have been placed with the following firms by the Stores Committee:—Dorman & Smith; Edison & Swan United Electric Light Co., Ltd.; Elco Recording Press; General Electric Co., Ltd.; A. P. Lundberg & Sons; Nettlefold & Sons, Ltd.; Perfecta Seamless Steel Tube & Conduit Co., Ltd.; Siemens Bros. & Co., Ltd.; Siemens Bros.' Dynamo Works, Ltd.; G. Straus & Co., Ltd.; Veritys, Ltd.; and Wm. White & Co.

The tender of Messrs. George MacLellan & Co. has been accepted for insulating materials.

The tender of Messrs. Dick, Kerr & Co., Ltd., has been accepted at £40,792 for the roadwork and platelaying in connection with the tramways from Rainton Road to Chapel Street, Woolwich, and also between Clerkenwell Road and Charles Street, Farringdon Road.

The tenders of Messrs. Alex. Stark & Sons, at £32,528, has been accepted for the roadwork and platelaying in connection with the Woolwich-Eltham tramways.

The following tenders have been received for the manufacture, supply, and erection of overhead electrical equipment of the tramways from Beresford Square, Woolwich, to Eltham:—British Insulated & Helsby Cables, Ltd. (accepted), £5,760; Sydney G. Smith, £5,870; Robt. W. Blackwell & Co., Ltd., £5,900 14s.; Dick, Kerr & Co., Ltd., £5,908 15s.; and National Electric Construction Co., Ltd., £5,056 9s. The tender of Messrs. Hadfield's Steel Foundry Co., Ltd., at £113 15s., has been accepted for special trackwork in connection with the above tramways.

LOWESTOFT.—The following tenders have been accepted by the Electricity Committee:—Messrs. Spagnoletti & Co., Ltd., two new feeder panels, £8 5s.; boiler tubes, Messrs. Babcock & Wilcox, Ltd., £105; the tenders of Messrs. Drake & Gorham, Ltd., and Messrs. Aubert Grenier & Co., for the supply of lamps and service cables respectively, have also been accepted.

MUSSELBURGH.—The tender of the Musselburgh & District Electric Lighting and Traction Co., for the lighting of the principal streets, on a three years' contract, has been accepted.

PORTSMOUTH.—The following tenders have been accepted

Digitized by Google

by the Council:—Section rails and fish plates, Messrs. Dick, Kerr & Co., Ltd.; tie bars, Messrs. C. Richards & Sons; cable, Messrs. Henley's Telegraph Works Co., Ltd.; arc lamp carbons, The Oliver Arc Lamp Co., Ltd.

WALSALL.—The following tenders have been accepted by the Tramways Department for annual supplies:—British Thomson-Houston Co., Ltd., armature coils, mica cones and collars, and commutator segments; Siemens Bros. & Co., Ltd., linen frame tape and linen tape; Henley's Telegraph Works Co., Ltd., B. & P. tape and Blackley tape; The British Insulated & Helsby Cables, Ltd., mechanical ears; Edison & Swan United Electric Light Co., Ltd., lamps; National Rail & Tramway Appliances Co., Ltd., brake blocks.

WEST AFRICA.—*Commercial Intelligence* states that the following firms have tendered for the supply of electric cranes to the Port of Lourenço Marques:—Messrs. Dick, Kerr & Co., Messrs. Cowans, Sheldon & Co., Messrs. Ransomes & Rapier, Messrs. Fried. Krupp, and Messrs. Nagel & Kaemp, of Hamburg. The Director of the Port and Railways has the contracts under consideration.

The D.P. Battery Co. have installed, or have now on order, batteries for 20 central stations, including a large battery of over 2,500 ampere-hours' capacity at 550 volts for the Corporation of Dudley, as well as others for the East Indian Railway at Howrah of 862 kw.-hours' capacity, for the Colonial Government at the Bahamas, the Liverpool & District Co., Manchester Corporation, and nine installations for Australia.

Among recent contracts awarded to Messrs. E. Bennis & Co., Ltd., are the following:—The Richmond (Surrey) Electric Light & Power Co., Ltd.: Four "Bennis" stokers and compressed-air furnaces for Davey-Paxman boilers (repeat order). Long Eaton U.D.C. Electricity Works: Two "Bennis" high-duty smokeless and gritless coking stokers and compressed-air furnaces for a Lancs. boiler (repeat order). Lincoln Corporation Electricity Works: Four "Bennis" stokers and compressed-air furnaces for dry back type boilers (repeat order). Daniel Adamson & Co. (for shipment to India for the Bengal-Nagpur Railway): Four "Bennis" high-duty smokeless and gritless coking stokers and compressed-air furnaces for Lancs. boilers.

COMPANIES' MEETINGS AND REPORTS

ISLE OF THANET LIGHTING & TRAMWAYS CO.—At the annual meeting on Thursday, the report and accounts given in our issue for December 9th were adopted. Lord Arthur Butler, referring to the appointment last year of a committee to confer with the directors on certain technical matters, regretted that no good results had accrued. One of the suggestions of this committee was that the supply for lighting should be changed from direct current to alternating current in order to utilise metal filament lamps more fully. The capital expenditure to carry this out would be very heavy, and an independent electrical engineer had agreed with the Board that it would be impracticable. Mr. W. M. Murphy said the directors were always willing to consider suggestions, but it would be intolerable to have a permanent committee criticising their actions. If the company were allowed to work out its own salvation, he had every faith in the undertaking. All tramway companies had been having a bad time during the past few years.

SHANGHAI ELECTRIC CONSTRUCTION CO.—At the annual meeting last week, the report and accounts were adopted. Sir Alfred Dent, chairman of the company, who presided, said the receipts during the past year had gone up, and the expenses had been reduced. He said the company was suffering enormous losses in exchange by having to take fares in depreciated Chinese silver and copper currency, whereas all their disbursements were in standard Mexican dollars. The company was now asking for a modification of the terms of their concession in order to put the undertaking on a better basis.

MELBOURNE ELECTRIC SUPPLY CO. The report for the year to August 31st shows a net profit of £12,721. After meeting the 7 per cent. first preference dividend, transferring £5,123 to depreciation and general reserve, and writing down to suspense account £2,039, there is a balance of £3,694, which is carried forward.

APPOINTMENTS AND PERSONAL NOTES

Mr. Cragg, third engineer-in-charge, at the Bermondsey Electricity Works, has been promoted to second engineer-in-charge at a salary of £170 per annum.

The Ilford District Council invite applications for the position of Tramway Manager, at a salary of £700 per annum, rising to £900. Particulars from the Town Clerk, and applications by January 10th.

Mr. L. B. Hogarth, of Bermondsey, has been appointed borough electrical engineer at Morecambe, at a salary of £150 per annum.

Mr. H. T. Wilkinson has resigned his position as Assistant Manager of the Chloride Electrical Storage Co., Ltd., and has joined the Wardle Engineering Co., Ltd., as Managing Director, conjointly with Mr. C. H. K. Chamen.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £61 15s. to £62 5s. per ton (last week, £61 10s. to £62).

CANADIAN AGENCIES WANTED.—A Lancashire firm manufacturing electric cranes, winches, and lifts, requires the names of Canadian importers of such machinery.

An Ottawa firm of general agents for mechanical and electrical supplies wishes to represent firms manufacturing such goods.

A Lancashire company manufacturing elevators and hoists of all kinds asks to be placed in correspondence with Canadian importers.

A London company manufacturing plugs and switches of all kinds, and electric light regulators, desires Canadian firms to represent them.

The names and addresses of the firms in question may be obtained at the office of the High Commissioner for Canada, 17 Victoria Street, London.

BANKRUPTCIES, LIQUIDATIONS, WINDINGS-UP, &c.—The Bradford Electrical Engineering Co., Ltd., is to be wound up voluntarily. Mr. J. H. Haley, Tyrrel Street, Bradford, and Mr. G. E. Corfield, Balfour House, Finsbury Pavement, London, are liquidators. A meeting of creditors was held at Queen's Hotel, Boar Lane, Leeds, yesterday.

A meeting of the Morris-Hawkins Electrical Co., Ltd., will be held at 58 Coleman Street, London, on January 12th, at twelve noon, for the purpose of hearing the liquidator's account of the winding up.

A meeting of creditors of the Bradford Engineering Co., Ltd., was held at the Queen's Hotel, Leeds, on Thursday. The company was incorporated on October 30th, 1909, with a nominal capital of £3,000. The statement of affairs shows total liabilities of £1,309, and assets £924. An Advisory Committee was formed to act for the liquidators.

A meeting of the Electrical Ore Finding Co., Ltd., will be held at the office of the liquidator, Suffolk House, Laurence Pountney Hill, London, on January 18th, at 2 p.m., to receive an account of the winding-up.

Mackey's Electric Lamp Co., Ltd., is to be wound up voluntarily. A meeting of creditors will be held at the Manchester Hotel, Aldersgate Street, London, to-morrow, Friday, at 11 a.m.

The Electro-Peat Coal Co. is to be wound up voluntarily.

ORDNANCE ATHLETIC CLUB.—The football section of the Electric Ordnance & Accessories Co.'s athletic club held a smoking concert last week in Birmingham, at which 400 of the staff were present. A very enjoyable programme was given, and the meeting was concluded with a vote of thanks to Mr J. R. Garner, the works manager, who took the chair.

DISSOLUTION OF PARTNERSHIP.—The partnership between C. H. S. Naylor and H. Broadhead, electrical engineers, 49 Ducie Street, Manchester, has been dissolved. C. H. S. Naylor will continue.

"IMPERIAL" WATER-TUBE BOILERS.—After official inspection of "Imperial" Water-tube Boilers, the Admiralty have placed Messrs. E. Danks and Co., of Oldbury, upon their list of manufacturers of water-tube boilers. The Water-tube Boiler and Engineering Co., 11 Queen Victoria Street, London, will supply full information.

MORRIS-HAWKINS, LTD.—We are asked to state that Messrs. Morris-Hawkins, Ltd., has no connection whatever with the Morris-Hawkins Electrical Co., Ltd., the public notice of the winding-up of which is made above. The works of Messrs. Morris-Hawkins, Ltd., are at Dagenham, Essex, the head office being at 30 St. Mary Axe, London.

MISCELLANEOUS CITY NOTES

PRIMITIVA GAS & ELECTRIC LIGHT CO.—A contract has been entered into between this Company and the Buenos Aires Municipality permitting an amalgamation of the Company with the River Plate Gas Co., Ltd., and the Buenos Aires (New) Gas Co., Ltd.

WINNIPEG ELECTRIC RAILWAY CO.—A dividend of 2½ per cent. has been declared for the quarter to December 31st.

CANADIAN GENERAL ELECTRIC CO.—A dividend of 1¾ per cent. is announced on the ordinary shares for the December quarter.

EASTERN TELEGRAPH CO.—A quarterly dividend of 1¼ per cent., free of tax, has been declared.

Breach of Mining Regulations.—At Aberavon, on Monday, Albert Gatehouse, a night electrician at Messrs. Baldwins' colliery at Bryn, near Port Talbot, was fined 30s. and costs for sleeping whilst in charge of the electrical equipment, and 10s. and costs for failing to register at least once in two hours the number of strokes per minute made by the ventilating apparatus at the colliery and the pressure shown by the water gauge. The latter is a violation of Special Rule 116, and the former offence a breach of Special Rule 236.

SUMMARY

A communicated article deals with the qualities and testing of transformer oil, and indicates the principal qualities which oil for insulating purposes should have, and describes some of the more simple tests which can be applied to samples of oil to gauge their suitability. (Page 1093.)

The following books are reviewed in this issue:—"Drawings for Medium-sized Repetition Work," by R. D. Spinney; "Arithmetic of Electrical Measurements," by W. R. P. Hobbs; "Making Wireless Outfits," by Newton Harrison; "Deinhardt-Schlomann Series of Technical Dictionaries in Six Languages," Vol. V.; and the "*Mechanical World* Electrical Pocket Book for 1910." (Page 1094.)

The Société Energie Electrique du Littoral Méditerranéen, formed in 1900 for the supply of electricity in the south of France, now obtains power from seven large water-power stations and nine steam stations, with total generating capacities of 56,500 h.p. and 23,100 h.p. respectively. These stations are connected together by a number of transmission lines carrying three-phase current at 50,000 volts and at lower pressures. The alternating current is generated and distributed at two different frequencies, and there are both A.-C. and D.-C. systems of distribution. (Page 1095.)

Some particulars with regard to the results of four years' working on the Borinage single-phase railway have been published. The total energy consumption of the system, including lighting and other items, works out at 1,700 watt-hours per train-mile, and the total working costs for 1908 were 6·34d. per train-mile. (Page 1096.)

An article by Mr. W. Copeland describes a new form of insulator for overhead lines in which binding wires are entirely dispensed with. This has a particular advantage in the case of aluminium lines. (Page 1096.)

A Paper read recently before the Dublin Local Section of the Institution of Electrical Engineers describes a system of electrical point shifting, in which the movement of the point is controlled by the current being on or off the car motors when passing certain overhead contact devices. (Page 1097.)

In a Paper read before the Institute of Marine Engineers, Mr. J. M. Newall described some ships' telegraphs and systems for affording communication between navigating officer and engineer, with special reference to his own apparatus for signalling and recording automatically how each order is carried out. (Page 1098.)

Under "Electrometallurgy and Electrochemistry" is given a description of the Côte and Pierron process of electrolytic zinc smelting and some notes on the purification of water by ozone. Some particulars are also given of a commercial method of producing thin plates of electrolytic iron. (Page 1099.)

A railway turntable erected in a station yard in Vienna is rotated by a locomotive with a single wheel driven by a 9-h.p. three-phase motor. This locomotive runs on the single rail in the pit of the turntable, and

Digitized by Google

current is supplied from three overhead wires by means of a roller collector fixed at the top of a pole in the centre of the turntable. (Page 1100.)

OPPOSITION is being made to the grant of a patent to C. Gilbert for an arc lamp feeding mechanism, comprising a ratchet wheel controlled by two independent pawls. The opponent is Mr. H. P. Bleckley, of the Abbey Electric Co. (Page 1101.)

AN interesting patent taken out by the Lancashire Dynamo & Motor Co., A. P. Wood and R. S. McLeod, was published last Thursday. It describes a frequency changer, comprising two coupled alternators, the armature of one of which is capable of rotation about the rotor axis and is geared to an auxiliary motor. If the frequency on either side varies from the normal and thus disturbs the ratio, the one armature is automatically rotated and compensates for the change. (Page 1101.)

IN a short Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, Mr. H. Morris Airey pointed out that certain observed inequalities in the rate of growth and decay of retinal stimulus to different coloured lights may be expected to introduce inaccuracies in the indications of the flicker photometer, especially where light of different colours are being compared. (Page 1102.)

A 20-TON accumulator locomotive equipped with a battery of 408 Edison cells, weighing 9·5 tons, is in service in Germany. Two 35-h.p. motors with series-parallel control are geared to the driving axles. On test, a distance of 132 miles was run on one charge with a loaded truck weighing 36 tons. (Page 1102.)

A TUNNEL for both pedestrian and vehicular traffic is being constructed under the River Elbe at Hamburg. It comprises two tubes under the river bed, connected with the surface at each end by means of shafts. Each shaft will contain six lifts, four for heavy vehicles, and two for passengers. The lifts will be electrically operated and automatically controlled. (Page 1103.)

AMONG the specifications published by the Patent Office on Thursday last was one by A. West, for a porcelain fuse carrier with spring contact checks at the extremities.—A process for producing pure tantalum has been protected by the Siemens & Halske Akt.-Ges.—E. von Lepel has patented a method of supplying oscillatory circuits by alternately charging from the supply, and discharging into the circuit, a battery of condensers.—A high-resistance material, comprising an alloy of silicon and tellurium, is covered by the British Thomson-Houston Co.—Opposition has been entered to the grant of a patent to J. Keith for a ship's ventilating apparatus, with means for adjusting the heating or cooling of the air.—Swan's Patents, Ltd., have applied for a further amendment to the patent covering a lamp cap with the shell and contacts interlocked with a glass.—The amendment of the patent covering the Freund track brake has also been applied for. (Page 1104.)

THE company supplying the city of Tokyo with electric light and power has a large water-power station some 47 miles from the city, and transmits the power at 57,000 volts, three-phase, over a double wooden-pole line. The station contains six turbo-generators of 3,900 k.v.a. each, generating at 6,600 volts. Additional water-power to yield a further 50,000 h.p. is being developed. (Page 1105.)

IN their annual Trade Review, Messrs. Bolling & Lowe deal with the copper market in 1909, and refer to the possibility of the control of North American production. (Page 1105.)

A LAMPHOLDER suspension clip is described on page 1106.

THE Electrical Association of Queensland has asked the Queensland Minister of Works to modify the electric lighting law with regard to overhead wires.—Mr. J. F. C. Snell recommends the Gillingham Council to install a Diesel engine-alternator in preference to taking a supply in bulk from the Kent Electric Power Co.—An action for vibration from electrical machinery is being heard at Hanley.—It was stated that the Yarmouth Pier fire was due to electrical causes, but as a matter of fact no electrical mains were on the pier in question. (Page 1106.)

BRIGHTON Corporation require a 3,000-kw. turbo-alternator, a 1,300-h.p. three-phase induction motor, high-tension switchgear, &c.—Eccles Corporation require a 150-kw. generating set; Eastbourne Corporation, condensing plant; and the Erith Council an A.-C. switchboard.—Tenders are invited for the wiring of the Institution of Electrical Engineers' new building.—Extensions are contemplated at Mansfield.—A large quantity of electric lamps and lampholders are required by the Italian Ministry of Marine. (Page 1107.)

THE accounts of the Sunderland & District Tramways Co. show a loss of £780 for the past year, and an accumulated loss to date of £14,604.—Large increases are proposed in the capital of the Mexican Light & Power Co.—The dividend on the preference shares of the London United Tramways, due on January 1st, is not to be paid.—The accounts of the Durham Collieries Electric Power Co. to September 30th show a loss of £21,713. (Page 1108.)

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, DECEMBER 30TH.

Royal Institution.

3 p.m. Juvenile Lecture II., "Electrical Instruments," by W. Duddell, F.R.S.

SATURDAY, JANUARY 1ST.

Royal Institution.

3 p.m. Juvenile Lecture III., "Röntgen Rays," by W. Duddell, F.R.S.

TUESDAY, JANUARY 4TH.

Royal Institution.

3 p.m. Juvenile Lecture IV., "The Generation of Electricity," by W. Duddell, F.R.S.

THURSDAY, JANUARY 6TH.

Royal Institution.

3 p.m. Juvenile Lecture V., "Electric Oscillations," by W. Duddell, F.R.S.

Röntgen Society.

8.15 p.m. At 20 Hanover Square, London. Paper by Dr. W. S. Lazarus-Barlow.

FRIDAY, JANUARY 7TH.

Institution of Mechanical Engineers.

8 p.m. At Storey's Gate, St. James's Park, London. "An Account of a Visit to the Power Plant of the Ontario Power Co., at Niagara Falls," by C. W. Jordan.

Electro Harmonic Society.

8 p.m. Smoking Concert at Holborn Restaurant, London.

SATURDAY, JANUARY 8TH.

Royal Institution.

3 p.m. Juvenile Lecture VI., "Electric Lighting," by W. Duddell, F.R.S.

BINDING VOLUME V. OF "ELECTRICAL ENGINEERING"

JANUARY to DECEMBER, 1909.

Subscribers' Numbers, sent to us Carriage Paid, will be bound in strong dark red Art Linen, with strengthened corners and back, and returned to any address in the United Kingdom, Carriage Paid, for 4s. 6d. Binding Cases only, 2s. each, or 2s. 4d. by post. (Colonies and Abroad, 2s. 6d.) Volumes for the Colonies and Abroad will be sent Carriage Forward.

The Index to Vol. V. will be ready on Jan. 6, 1910. Price 1d. (Post Free, 2d). It will be supplied free of charge with binding cases and binding orders.

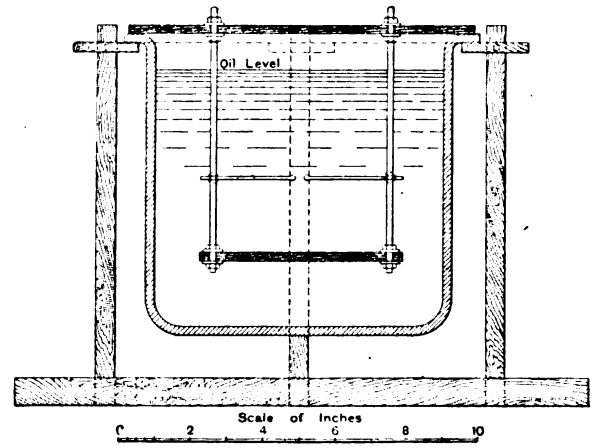
QUALITIES AND TESTING OF TRANSFORMER OIL

Communicated

UNTIL twenty years ago oil, as an insulator for high-tension work, had received little attention. With the development of high-voltage systems the question, in the early 'nineties, received considerable investigation, and many tests were carried out, especially in the United States; but it was not until the last few years that the manufacturers specialised in producing a sound oil of high dielectric strength, and, after careful research, placed such an oil upon the market. At the present moment there are at least half a score of firms in this country who have evolved such an oil, and the annual output and consumption of transformer oil have assumed very extensive dimensions, so that the question of its selection and supply is of first importance.



When inviting tenders for electrical equipment, including transformers, it is not the custom, at least in this country, for the buyer to make a specification for the oil to be used. That is to say, such questions as the flashing-point, burning-point, viscosity, and degree of evaporation are not insisted upon, but the insulation test of the assembled transformer is taken to cover such a specification. If the oil is of such a quality that the transformer will successfully pass its high potential test, the fact is taken as a guarantee of its quality. This is perfectly rational, and is, besides, of great convenience to the manufacturer, as he has rarely the electrical appliances at hand necessary for the carrying out of the breaking-down tests called for. These tests are therefore carried out at the shops of the electrical manufacturers, usually not on the oil alone, but on the whole transformer immersed in oil in its case.

Although the high-potential test on the oil is one difficult to carry out unless the necessary appliances are at hand, the buyer of the oil may easily make a few simple experiments which will show up any pronounced faults. The causes of a low dielectric strength being, broadly, moisture and impurities, he may test for the former by placing some of the oil in any small vessel, and plunging into it a piece of iron which has been brought up to a dull red heat. A sharp hissing noise will occur if there is much moisture in the oil, while a dry oil will cause practically no such hissing. Another simple test is to pour a little of the oil on to some anhydrous copper sulphate, when, after being shaken well in any suitable vessel, the copper sulphate will turn a bluish colour if there is moisture present. As regards testing for impurities, the presence of any acids or alkalis may be detected with litmus paper. Any solid impurities, such as dirt, carbon deposit, &c., may be seen by running a little of the oil slowly out of a glass bottle, the bottle being held to a good light. An oil showing such particles should be at once rejected, though very often it would be quite sound for all practical purposes after careful filtration. Though these are rough-and-ready tests, they are quite capable of showing up a really bad oil.

The best oil for insulation purposes is a mineral oil. It is difficult, in the light of present knowledge, to say whether a heavy mineral oil is, as a general rule, a better insulator than a light mineral oil. My own results, from tests taken on oils which have been thoroughly dehydrated, show that there is very little difference between heavy and light oils. From this it would not be right to generalise and say that for practical service the insulating qualities of the two are equal, because the question of the relative moisture-absorbing or moisture-carrying capacities now comes in. Assuming that one drop of oil is made up of millions of molecules, it is agreed that these molecules are larger for a heavy oil than for a light oil, though there are certain exceptions to this rule. Now, any water which the oil is carrying is not in chemical combination with the oil, but is mechanically suspended in the interstices between these molecules. It is therefore obvious that a heavy oil, having large molecules, has a greater capacity for carrying moisture than a light oil, and must therefore be adjudged an inferior insulating agent. If moisture has been absolutely removed from both oils, then the question of the moisture-carrying capacity does not matter, and the *apparent* dielectric strength, as registered on the voltmeter, will depend simply on the *actual* dielectric strength of the ultimate particles. It is this actual dielectric strength of the hydro-carbon molecules which is, according to my results, practically uniform for all mineral oils. There is a slight difference, and it seems to be in favour of the heavy oils. The reason for this I take to be as follows:—Suppose there is a high potential difference between two metallic contacts immersed in oil. Any moisture in the oil will be attracted and will line up across the gap. If the molecules composing that oil are infinitely small, then the particles of water will lie along a straight line. If the molecules of the oil are large, then the line upon which the particles of water will lie will be zig-zag; and therefore in the second case, in stepping across the gap by means of the water, the volts will have a longer path to traverse, and will consequently show a greater reluctance to do it. With few exceptions a heavy oil has larger molecules than a light oil, and the above is the reason I have assigned for the fact that when both are thoroughly dry, a heavy oil possesses a slightly higher apparent dielectric strength than a light oil.

To quote actual figures as to what results may be expected, I should say that, using a 0·2-in. gap, with flat plate contacts, any pure dry mineral oil breaks down between 14,000 and 20,000 volts. With needle contacts these limits would be reduced to about 9,000 and 13,000. The curve connecting gap and breakdown pressure being approximately a straight line, we may say that the average good transformer oil, when sent out by the makers, will break down across a 1-in. gap somewhere between 70,000 and 100,000 volts with plate contacts, somewhere between 45,000 and 60,000 volts with needles.

It is the qualities of purity and dryness which cause an oil to be good or bad, and they are therefore the questions receiving chief consideration from the manufacturer. To illustrate this I may say that I tested an oil with a ¼-in. gap, and it succeeded in withstanding a pressure of 19,800 volts. I left the barrel of oil exposed to the air in a damp shed for 48 hours, and then broke it down at 13,000 volts with the same gap. I then introduced a few drops of water into the oil, and disseminated the moisture thoroughly. It then failed to stand up to 8,000 volts, the lowest voltage I could obtain with the alternator I was using. To illustrate the deterioration due to impurity, I quote a case I read of. A transformer was in active service for a year, with the oil constantly at a high temperature, and with the insulation resistance allowing a large

OIL-TESTING APPARATUS.

factor of safety. The introduction of a few grains of sulphur into the oil was sufficient speedily to bring the value down to the breaking point.

To ensure obtaining a pure oil, the natural oil should be subjected to fractional distillation, and dried and sealed without chemical treatment of any kind. The two commonest methods of drying an oil are by baking in an oven, and by dehydrating with metallic sodium. Of these the former method is the more to be recommended, as it requires the introduction of no foreign substance whatever. There are some manufacturers of transformers I know who have in their winding or insulating shops ovens capable of holding as many as a dozen barrels of oil. If any oil to be supplied to the customer falls below a given high potential standard, and moisture is suspected, the barrels are placed inside the ovens, where a temperature of 180° F. is maintained for one, two, or three days, samples being taken from the barrels periodically and tested for breakdown. I have known oil which broke down at 50,000 volts per inch lose its moisture in twelve hours in the oven, and maintain a pressure of 95,000 volts. During the baking process the lid of the barrel should be removed to allow the heat to get well into the oil, and also to afford an overflow due to the oil's expansion. The oil should also be frequently stirred, in order to bring all the contents of the barrel in turn to the place of greatest heat.

In the sodium method of drying oil, the sodium is generally introduced into the oil by means of a wire bag, and it is advisable to place as many of these bags in the tank as possible. The oxygen of any water present combines with the sodium to form caustic soda, while the hydrogen is liberated The action must be watched, as if there is much moisture it is possible for the hydrogen to be evolved too freely. I am not in favour of the attempts which have sometimes been made to perform this operation while the transformer is in actual service, as I consider the practice a highly dangerous one. If a little sodium were introduced in the oil-space above the iron of the transformer, little risk would be run; but in that case the oil at the bottom of the case would stand little chance of becoming dehydrated. It is obvious that to drop the sodium into the bottom of the case would be almost like inviting an earth.

When once a good oil has been obtained from the manufac-

Digitized by Google

turer, the buyer should see that the transformer case is clean and dry before the oil is poured in, and no time should be lost before the cover of the case is put on. Oil purchased from the makers and kept on the buyer's premises should be kept, if possible, in a dry, though not necessarily warm, place, the barrels in no case being left exposed to the damp. If the covers are always kept on the transformers, the oil will deteriorate very little, and no alarm should be felt at the sight of the dark-brown deposit in the oil. This deposit is formed by the action of the heat on the insulating varnishes of the windings, and is probably as good an insulator as the oil itself. At the same time, however, it is as well to clean out the transformer periodically and remove this deposit, as it is liable to hinder the cooling action of the oil by frequently blocking up the ventilating passages of the transformer.

In taking tests upon the breakdown point of oils, I have used an alternator with a smooth-core armature capable of giving 120 volts on a full excitation at 50 cycles, and a transformer with a ratio of 200 turns to one. The diagram shows a vessel in which to carry out the puncture test, and is similar to the one I have used, one or two dimensions being slightly different, and the gap contacts being balls instead of the ¼-in. flat plates with which I have made most of my tests.

The cylindrical glass jar is hung on the four supports by means of the lip which runs round the top. The oil should then be poured in, and the framework, consisting of two ebonite bars, ⅜ in. thick, held together by the two ¼-in. brass rods which deliver the breaking potential, should then be placed in the oil, with the ebonite resting on the lip of the jar. The gap is adjusted by two screws working on the two $\frac{1}{10}$-in. brass rods, any accurate feeler being inserted for measuring the distance. The inside ends of these two rods constitute the two points between which the potential is applied. The high-tension leads, single-strand copper, are wound round the tops of the vertical rods and secured by the nuts.

The following points must be watched in testing oils. The first thing to bear in mind is that if comparisons between any oils, or between any oil and a standard, are to be made, uniformity in method and apparatus must be observed. The same generator should always be used. As I mentioned above, I have usually employed a smooth-core machine with a flat-top wave; but this is acting with leniency to the oil, as, of course, a peaky wave of the same root-mean-square E.M.F. will break down any insulation more quickly than a flat-top wave. Provided the E.M.F. waves of two machines are similar, the individual results will stand comparison. The speed of the alternator does not matter a great deal. As a matter of fact, between large limits of periodicity, there is a variation in the effect on any dielectric, but for all ordinary frequencies the difference is small. The volts should always be applied in the same way, the best way being to start with the field rheostat all in and gradually bring up the field. The time of application should be the same. The depth of oil above the spark-gap should be constant, as the apparent dielectric strength depends upon the mechanical pressure on the oil. It is advisable to allow the oil to stand in the jar for a few minutes before applying the volts, as any air carried into the vessels reduces its apparent dielectric strength, and a wait should be made until all air-bubbles have come to the surface. It would seem superfluous to mention that scrupulous cleanliness is essential, or the results are worthless. I have, unfortunately, often found that with a careless tester, all deposits are not cleaned out between tests, apparently in ignorance of the fact that a single hair from a ball of cotton waste is capable of breaking down the oil, if it should line up between the contacts at the correct psychological moment. Apart from the walls of the jar, it is necessary to clean the contacts thoroughly after each puncture, for a twofold reason. One-hundredth of an inch deposit represents 1,000 volts with a good oil, and, further, any roughness or dirt on the contact changes the apparent dielectric strength.

I have sometimes noticed in testing a sample of oil that there occurs a slight sputter as of a puncture, but not so pronounced as the usual bubbling noise made when the volts step across, the reading on the meter sometimes being hardly affected by it. It is necessary to watch for this very closely. It occurs when there is a very slight trace of moisture, and, when it is observed, the sample must be poured off and a fresh one put in, for the reason that during that one slight combustion a drying action took place in the oil, thus sending up the apparent dielectric strength to a higher, but untrue, value. To illustrate this, I may say that I was once working with a 0·2-in. gap, and broke down a sample at 11,000 volts. Without removing the oil, I raised the volts again, and found that at *38,000* the same sample was still good!

On occasion, while testing very heavy oils, I have noticed the formation of an explosive mixture. A heavy oil is usually an oil rich in carbon, and after one breakdown of the oil and the consequent high temperature produced across the gap, the oxygen of the water combines with the carbon to form carbon-monoxide. This gas rises to the surface, and contact with the air causes the formation of a highly explosive gas. On a further breakdown occurring in the oil, this mixture will usually be ignited, and will explode with a loud report. On one occasion the concussion was sufficient to shatter the glass jar with which I was working to fragments. For this reason I had a jar made, as in the illustration, of a heavy glass ¼ in. thick.

REVIEWS OF BOOKS

Drawings for Medium Sized Repetition Work. By R. D. Spinney. 91 pp. 5½ ins. by 8½ ins. 47 illustrations (London: E. & F. N. Spon.) Price 3s. 6d.

THE author addresses himself principally to engineers supervising the preparation of detail drawings of machine parts to be standardised and made in quantity, and considers the various parts of the subject both from the point of view of drawing-office routine and manufacturing conditions. Although most of his illustrations are taken from the field of automobile construction, there is much in the general principles enunciated which applies to practically all classes of manufacturing engineering. The chapter entitled "Tolerances" is particularly useful, and deals clearly with the limits of accuracy to be aimed at and how their attainment is to be ensured. Another portion gives some notes on designing for repetition work, which are full of suggestions as to where manufacturing costs can be considerably reduced by small changes in design, and multiplicity of standard patterns avoided.

Arithmetic of Electrical Measurements. By W. R. P. Hobbs. Thirteenth Edition. 126 pp. 7¼ in. by 4¾ in. (London: Thomas Murby.) 1s.

THE fact that this is the thirteenth edition of this little book speaks well for its contents. No important alterations or additions have been made since the eleventh edition, which was revised and enlarged to form the twelfth. It comprises twelve short chapters, covering the application of Ohm's law to simple problems of resistance, and of the connection of galvanometers, cells, lamps, and dynamos. The feature of the book is the large number of worked examples, while each chapter is followed by a collection of questions with answers, many of which have been taken from the examination papers of the City and Guilds of London Institute.

Making Wireless Outfits. By Newton Harrison. 61 pp. 5 in. by 7¼ in. 27 illustrations. (London: E. and F. N. Spon.) 1s. 6d. net.

WITH the aid of this little book, which is of American origin, an intelligent amateur would doubtless be able to construct a model set of wireless apparatus of the simplest kind, namely, a set comprising an induction coil and spark gap at the transmitting station, and a filings coherer and relay at the receiving end. The functions of the various pieces of apparatus involved are not, however, very clearly or accurately explained.

Deinhardt-Schlomann Series of Technical Dictionaries in Six Languages. Vol. V.: Railway Construction and Operation. 870 pp. 7 in. by 4 in. Illustrated. (London: Archibald Constable and Co.) 12s.

THE fifth volume of this series of technical dictionaries is arranged in the same way as the previous volumes on other branches of engineering, that is to say, the ideas are arranged according to subject matter with the German, English, and French expressions on one side of the page, and the Russian, Italian, and Spanish on the other, while suitable illustrations are given in the central space. The latter part of the book consists of alphabetical indices with the Russian words separately, owing to the difference in alphabet. As is perhaps natural, the illustrations remind one more of Continental than British railway practice. But the majority of English and American steam railway terms appear to be given correctly. There is a comprehensive section devoted to electric railways, covering a considerable range of electrical engineering; we are afraid, however, that a foreign reader would look in vain for the meaning of some of the special terms which have come into use in this country in connection with electric train equipments, such as "bus-line jumper receptacle," or "pigtail." Even such familiar expressions as "contactor," "master-controller," and even "multiple unit" system, are not to be found in the index, so that the electric railway section, though it contains numerous general electrical engineering terms, that could be found elsewhere, is very incomplete.

The "Mechanical World" Electrical Pocket Book for 1910. 6¼ in. by 4 in. 270 pp. (Manchester: Emmott & Co.) 6d.

THE first edition of this pocket book was published as a separate volume from the original "Mechanical World" Pocket Diary only two years ago, but already considerable revision has been necessitated by new developments, particularly with reference to electric lamps and lighting. New sections have also been introduced on motor-converters, new wiring systems, fuses, meters, time switches, aluminium cables, lightning conductors, and there has been other general revision. There is a pleasing absence of the redundant semi-historical matter which disfigures many pocket books, and the matter all through is commendably concise. We are pleased to see that a better quality of paper has been used than in the earlier editions.

POWER TRANSMISSION AND DISTRIBUTION IN THE SOUTH OF FRANCE

IN the year 1900, a company for the distribution of electric power in the south of France was formed under the name of the "Société Energie Electrique du Littoral Méditerranéen," with a capital of four million francs. This capital was raised to eight million francs in the following year in order to provide for the construction of a 5,000-h.p. water-power station at Pataras on the River Loup, and for the purchase of the 2,000-h.p. station at Mescla on the River Var, and of the competing business of the "Société des Forces Motrices des Alpes Maritimes." Already in the year 1902 over 9,000 h.p. was distributed, of which 3,000 h.p. was taken by the "Société Niçoise d'Electrochimie," for the manufacture of calcium carbide. The purchased system, which had been operated at 5,000 volts, 50 cycles, was changed to 10,000 volts, 25 cycles, the pressure and frequency of the main system, and served to supply the tramways of Nice and Cannes, and a large number of smaller consumers, including some large factories. In 1904 a 5,000-h.p. water-power station was constructed at Plan-du-Var on the Var for the supply of Toulon and the surrounding district with light and power, and a second station for 10,000 h.p. was commenced at Saint Cézaire on the Siagne. The capital was raised to 16 million francs in March, 1904, and it was then decided to construct a 14,000-h.p. station at Brillanne-Villeneuve on the Durance partly to supply energy for light, power, and tramways in Marseilles. In 1905, a new company was formed under the name of the "Sud Electrique," with a capital of 3·1 million francs, for the distribution of power in over two hundred districts, including those of Avignon, Nimes, Arles, Tarascon, and Montpellier. The last steps in the development of the system were the purchase in 1906 of water-power rights to the value of 20,000 h.p. in the Département des Basses-Alpes, and the agreement with the "Société des Forces Motrices de la Haute-Durance," by which the whole of the 30,000 h.p. of the water-power station at Ventavon on the Durance, then under construction, was put at the service of the "Société Energie Electrique du Littoral." This latter station has only been recently completed. In March, 1906, the share capital of the company was increased to 32 million francs.

The present state of the system is shown in the accompanying figure. In the Département des Alpes-Maritimes there are water-power stations with a total capacity of 20,000 h.p., and steam stations with a total capacity of 8,900 h.p. In the Département du Var the corresponding figures are: water-power, 2,500 h.p.; steam, 1,800 h.p. In the Département des Bouches du Rhône there are no water-power stations, but three steam stations with capacities of 8,000 h.p., 4,000 h.p., and 400 h.p.; the 4,000 h.p. station at Arles has Curtis turbines. The 14,000 h.p. water-power station at Brillanne-Villeneuve in the Département des Basses-Alpes is in full operation, and some 20,000 h.p. is already taken from the Ventavon station of the Société des Forces Motrices de la Haute-Durance in the Département des Hautes-Alpes. Besides the above, the company has further water-power rights to the amount of 66,000 h.p., and intends to install another 6,000 h.p. in steam reserve stations. Including these last, the totals are—water-power, 122,500 h.p., and steam, 29,100 h.p.

As can be seen from the figure, the departments are interconnected, and many of the steam stations only serve as reserves at times of shortage of water. The rivers Var and Durance have two periods of shortage, but the Verdon and Siagne only one, and these do not occur at exactly the same time; further, the maximum load occurs approximately at the period of maximum water supply, so that a large steam reserve is not necessary. The fact that the capacity of the steam stations is about 40 per cent. of the whole shows, therefore, that the development of the system has not only been due to the plentiful supply of water, but also to the great demand for power in these rich manufacturing districts.

OUTLINE MAP OF AREA SUPPLIED BY THE SOCIÉTÉ ENERGIE ELECTRIQUE DU LITTORAL MÉDITERRANÉEN.

The system works at various pressures and two different frequencies. The water-power stations deliver three-phase power at 10,000 v., 13,500 v., 30,000 v., and 50,000 v. at 25 cycles. That at Vis generates at 30,000 v. three-phase, 50 cycles. The steam station at Arles, which supplies both the "Sud Electrique" and the "Energie Electrique" networks, contains two 1,000 kw., 13,500 v., 25 cycle three-phase sets and one 50 cycle set, with Curtis turbines. The remaining steam stations generate at 25 cycles. In the sub-stations are transformers, motor-generators, rotary-converters, and frequency changers, according to the pressure and system of the local distributing networks.

There are some 370 miles of transmission lines at 50,000 volts. Steel masts spaced about 230 feet apart are employed, and the wires are supported on porcelain insulators weighing 17·5 lbs.

Digitized by Google

each, at a distance of 5·75 feet from each other. The height of the masts is about 33 feet. The wires at the lower pressures, 10,000 v. and 13,500 v., are supported immediately under the 50,000 volt wires, and under these are placed the telephone wires. The network of the Alpes-Maritimes is supplied at 11,000 v. from the stations at Mescla, Plan-du-Var, Loup, and Siagne; the secondary pressure is 2,200 v., while the distributing pressures are 230 v. and 115 v. The Var network includes double lines between Siagne and Entraigues and between the latter station and Toulon. Both the Alpes-Maritimes and the Var networks can receive power from Siagne. The secondary pressures of the Var network are 10,000 v. and 3,350 v., and the distributing pressures 230 v. and 115 v. The Bouches du Rhône network includes 50,000 volt lines from the Siagne, Durance, and Arles stations. Two separate companies in Marseilles distribute in that city, and these companies have two reserve steam stations. One of these is in the Quartier d'Arene, and has Curtis turbine sets with a total capacity of 17,000 h.p.

In all, according to the *Elektrotechnische Zeitschrift*, from which the above particulars are taken, the "Société Energie Electrique du Littoral Méditerranéen" supplies power to ten tramway systems and sixteen distributing undertakings. The system includes the direct supply of 256 townships, with a total of one and a half million inhabitants, and an indirect supply through distributing companies to 83 other townships, with some 150,000 inhabitants.

WORKING COSTS OF A SINGLE-PHASE RAILWAY

SOME particulars with regard to the working costs on the Borinage single-phase railway have been published in *Elektrische Kraftbetriebe und Bahnen*. This railway has some 21 km. of single track, and was opened to traffic in 1905. Current is supplied to the overhead line at 600 volts, 40 cycles. The commutator motors on the coaches are of the A.E.G. Winter-Eichberg type of 40 h.p. each on the one-hour rating, and run at a maximum speed of 800 r.p.m. There are two motors on each coach, and the total electrical equipment weights 3·7 tons. A normal train consists of one motor-coach and one trailer. A motor-coach weighs 10 tons unloaded, and has a seating capacity of 40, and the trailer with the same capacity weighs 4 tons.

The coaches run from 88 to 110 miles daily. Twelve coaches are in service on week-days, and from 15 to 18 on Sundays. The yearly number of train-miles run is about 400,000, and the average energy consumption of the whole system, including lighting, traction, and the power used in the repair shops, works out at about 1,700 watt-hours per train-mile. This figure was deduced by dividing the total output of the power-station by the number of useful train-miles, and includes also the losses in the transformers. The electrical equipment is said to have kept in good condition during the four years it has been in use. Commutators do not require grinding after 1,550 miles, and give no trouble with carbon brushes. The total working costs per train-mile have been approximately as follows: In 1905, 7d.; in 1906, 6·8d.; in 1907, 6·5d.; and in 1908, 6·34d. The traffic receipts having increased from £6,700 in 1906 to £10,050 in 1908, in spite of adverse circumstances.

Arc Lamps with Supported Carbons.—The Deutsche Beck Bogenlampen-Ges., of Frankfurt-on-Main, has taken out a patent in Germany (No. 203,817, dated April 15th, 1908), covering the use of solid silver or silver-plated stops for supporting the one carbon in flame arc lamps of the converging carbon pattern without feeding mechanism.

The South London Single-phase Railway.—It is stated that the results of the working of the South London Elevated Electric Railway have been so satisfactory that the desirability of extending this method of electric traction to other portions of the London, Brighton, & South Coast Railway Co.'s system is under consideration. The traffic on the line has shown a very great improvement as compared with the returns on the same section before conversion to electric traction took place, and a ten-minutes service is to be inaugurated on and after January 1st.

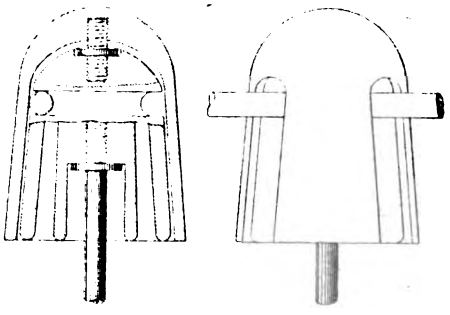
The Clapham Fire.—The inquest on the unfortunate victims of the fire at Messrs. Arding & Hobbs' premises at Clapham Junction was opened on Thursday, the inquiry being confined to the purposes of identification. As far as can be ascertained, seven persons perished in the fire. Mr. John Troutbeck, the Coroner, and the representatives of all parties interested, expressed sympathy with the relatives of the deceased. Among those present were the Mayor of Battersea; Mr. J. E. Haresden (Inspector of Factories); Mr. J. W. Godfrey (London County Council); Mr. J. J. Washington (South Metropolitan Gas Co.); and Mr. F. H. Bond (Electrical Engineer, Battersea Borough Council). The inquest was adjourned until Thursday.

A NEW INSULATOR FOR OVERHEAD LINES

By W. Copeland

HIGH-TENSION transmission lines, or even low-tension transmission lines are not so much in use in this country as they are on the Continent and America, although their adoption has increased somewhat during the last few years. The use of aluminium wire is also on the increase, as it is lighter to work with than copper, requires fewer poles, and the latter are more easily stayed. When dealing with this class of work the insulators are the most important feature. The greatest drawback with the aluminium wire is the binding, as nothing can be used for this purpose except aluminium itself. These have been the source of much trouble, owing to breakage, but the use of any other metal causes electrolytic corrosion. It is usually impossible to have all the poles at the same height on unlevel ground, and the strain on the binding wire is apt to be considerable. Where aluminium lines are employed, the author recommends the use of oak arms; and where there are several arms on poles wooden oak laths should be used in a vertical position to stay the arms. As little iron work should be used as possible, as it is expensive to maintain, and dangerous should the wire come into contact with it. All the iron work necessary is the earth wire, which should be carefully considered and well fitted from the top to the bottom of the pole. The insulator bolts to be used should be not less than ¾ in. in diameter, and insulators on the terminal pole ¾ sq. in. section, swan neck type. Shackle insulators are not to be recommended for such work.

The author has designed and patented an insulator which is to be manufactured by Messrs. James Macintyre & Co., Ltd., Burslem. This insulator can be used for all purposes on an installation, either on a straight line, curve, or terminal pole. It can be used for any class of wire—aluminium, bare copper, or insulated—and for telephone, telegraph, electric light, and



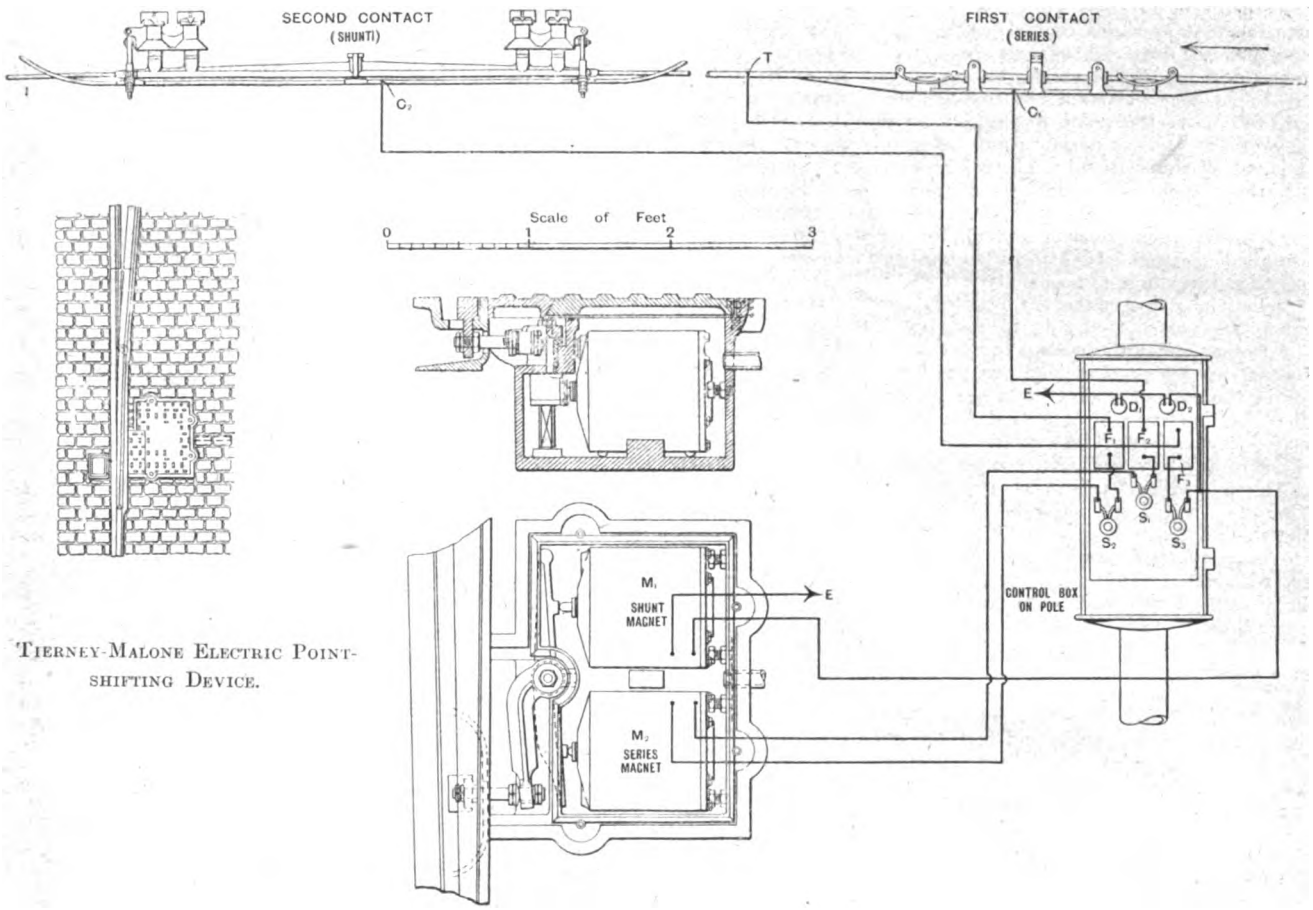


FIG. 1.—HIGH-VOLTAGE INSULATOR. FIG. 2.—LOW-VOLTAGE INSULATOR.

power, high- or low-tension transmission lines. A special feature about the insulator is that the outside cover can be made of any metal, pot, or porcelain, and when aluminium wires are used the cover of the insulator can be made of aluminium. Binding wires are dispensed with, and the insulator is practically unbreakable. Sketches of two forms of the insulator are given. That shown in Fig. 1 is recommended for high voltage work, and that shown in Fig. 2 for low voltages. The insulator is carried on an ordinary bolt, which has a square collar in order to hold or turn it by means of a key or otherwise. The body is an ordinary porcelain insulator with the usual studs, and has a horizontal groove round it which contains the wire, the latter projecting somewhat from the groove. On the top of the insulator is a screwed socket or stud bolt. This socket is entirely separated from the socket for holding the bolt by a sufficient thickness of porcelain. The stud bolt has an ordinary right-handed screw on each side of a central collar, and there is a cap, which can be made of porcelain or metals. This cap and insulator are preferably somewhat conical in shape, but the cap is rounded at the top. The mode of erection is as follows:—The bolt being screwed into the insulator in the usual manner, the stud being also screwed into the insulator, the bolt is put on its supports, but not tightened up. The line wire is placed in the groove, and the cap dropped over, resting on the stud. The cap is now held by the hand and guided centrally, and the bolt turned round until the upper screw of the stud screws tighten in the cap and holds the latter against the wire. The wire is now firmly fixed. This gives no trouble as regards binders when lines are far away, and when unbreakable covers are used it is another very valuable consideration for public roads.

AN ELECTRICAL POINT CONTROLLER FOR TRAMWAYS

MR. J. P. TIERNEY read a Paper on December 9th before the Dublin Local Section of the Institution of Electrical Engineers, in which he described the Tierney-Malone point-shifting device as used on the Dublin and other tramways. After giving particulars of the earlier experimental forms of the apparatus, he proceeded to describe in detail the standard equipment as it is now working on several systems, including Dublin, Belfast, Newcastle-on-Tyne, Salford, Hull, Birmingham, Stoke, and Bristol. Each point is always set for one particular line; the cars on this particular line do not move the point, but the cars going on the other line always move the point for themselves and set it back again after they have gone through. It has the advantages that motormen are able to see the point moving before they come up to it, and if the current should leave the line when the wheels of the car are going through the point, the point will not spring over, as it does not depend on the current for keeping it in any position. The fact of a point being fitted with the apparatus does not in any way prevent the point being operated by the ordinary bar should occasion arise.

TIERNEY-MALONE ELECTRIC POINT-SHIFTING DEVICE.

The point equipment is shown in the figure, and consists of a cast-iron box next to the point, with its cover flush with the street, containing two specially designed stopped solenoids (one series and one shunt). A steel spindle passes out through a packed gland to an outside chamber of the box. Mounted on the spindle inside the box is a lever having equal arms on each side of the spindle. This lever arm is at such a height that the nose of one solenoid plunger pushes against one arm of this lever and the nose of the second solenoid plunger pushes against the second arm of this lever. On top of this vertical spindle in the outside chamber is mounted a lever arm, connected by a rod to the tongue of the point. Thus, when one solenoid is energised, it pushes one arm of the inside lever, thereby giving a turning movement of about 15° to the vertical spindle; this in turn operates the outside lever arm, and thence the tongue of the point. When the other solenoid is energised, it pushes against the other arm of the inside lever, thereby giving a turning movement in the opposite direction to the vertical spindle and lever arm, consequently shifting the point in the opposite direction. The solenoids used are of the stopped type, but instead of the plungers pulling their work after them when sucked into the coil, as is the general practice, the stop of the solenoid is bored out, and a brass rod, screwed into the plunger, passes through the stop. By this means the solenoid plungers are used to push instead of to pull their work. This arrangement has the advantage that the plunger rod does not necessitate alignment.

The overhead-line equipment consists of two contacts. The first, or series contact, is placed about 50 ft. in front of the point. This gives the driver full opportunity of seeing that the point has been properly operated before he goes through; the second, or shunt contact, being placed at a suitable distance after the points. The series contact consists of a pair of inverted ramps, secured to the trolley wire. Between these ramps is a contact strip or centre-piece, insulated from the trolley wire. These are so arranged that a trolley passes along the underside of the ramp (and in doing so leaves the trolley wire), and from the ramp it passes on to an insulated inset, thence along the centre contact strip, under another insulated inset, along the second ramp, and thence on to the trolley wire again. By means of two bridging-pieces over the insulated insets there is no part of this contact from which the trolley cannot get current, so that, no matter what position a car stops in, it will have the necessary current to start off again. This centre contact strip is electrically connected to the trolley wire, through the series-wound solenoid placed in the street box at the point. Thus it will be seen that whatever current the car is taking from the line when the trolley is passing under this insulated contact strip will pass through the series solenoid in the street box at the point as the trolley head makes electrical connection with the centre contact strip. The second, or shunt contact, consists of an ordinary ear with two hubs attached in the usual manner under the trolley wire. Each of these hubs carries a special insulator, and these in turn carry between them a contact strip. This strip is insulated from the trolley wire, and is so suspended and placed that, when the trolley head of the car is passing under the ear, the side of the trolley head will rub against and make contact with the contact strip on the line. This contact strip is connected to the shunt solenoid in the street box through a suitable switch and fuse placed in a control box on the nearest street-pole. The other end of this solenoid is connected with the rail. A control box on the nearest pole contains three switches and three fuses. Two switches and two fuses enable the series solenoid to be entirely disconnected from the overhead-line contact when the

Digitized by Google

points are being examined or overhauled. The third switch and fuse performs the same operation for the shunt solenoid. In case of a fault developing on a magnet or a cable going to earth, the fuses protect the apparatus from damage and also protect the line from being grounded. Two 260-volt 16-c.p. lamps in the control box connected in series with each other are permanently connected between the wire connecting the second, or shunt, contact with the shunt solenoid and earth, and are therefore permanently in parallel with the shunt solenoid, thereby acting as a discharge resistance for the solenoid coil, and take up the back E.M.F. which would otherwise be set up owing to the solenoid being open-circuited. In the case of the series solenoid this function is performed by the bridging-pieces, as by their operation, when the trolley of the car is leaving the centre contact strip, it makes contact with the bridging-piece on the trailing end of the first contact before leaving the centre contact strip. This has the effect of short-circuiting the series solenoid before open-circuiting it, and consequently discharging the back E.M.F.

When the driver of a car approaches a point which it is necessary for him to move, he keeps his car controller on one of the operating positions while the trolley of his car is passing under the first or series contact. When the trolley of the car passes it will draw its current from this insulated contact, thereby drawing the current the car is taking through the series solenoid at the point, which solenoid, on becoming energised, will move the point to the desired position. When the trolley of the car has passed from under this contact the current is cut off this solenoid. The car having passed through the point, the trolley passes under the second, or shunt contact, which is then made electrically alive, thereby sending the current to the shunt solenoid, which throws the point back to its original position. If drivers do not require to move the point, they keep their car controller on the "off" position while the trolley is going under the first contact. It is immaterial whether the car controller is in the "on" or "off" position while passing under the second contact, either in the case of a car which has operated a point for itself, and requires to close it, or in the case of a car which has passed through the point in the direction for which the point is set. The length of the insulated contact strip, first contact, is only 18 in., so that it does not in any way inconvenience the motormen who require to drift through without power.

Where trailer-cars are employed this method would not apply, as the shutting back of a point by a car with a trailer attached would cause the motor-car to take one road and the trailer the other, whereas, if this second contact was placed so far ahead as to permit all the trailers to pass through before the point were shut back considerable delay would be caused during the slack period of the day when the single motor-cars would be running. To meet these conditions a modified arrangement has been designed, in which there is only one overhead contact instead of two, that one being the same identically as described above as the first or series contact, and being placed as before, 50 ft. in advance of the point. Each car requiring to open the point does so as explained above, but does not shut it back—*i.e.*, the car on each road makes the point for itself. The point box in this case contains only one solenoid. The system is equally applicable to conduit tramways by an arrangement of contacts on the conductors in the conduit.

The overhead frog on the trolley wire can be operated in connection with the track point if desired, or can be operated mechanically by automatic mechanism. At night the position of the point tongue can be shown to the motormen by coloured lights on the nearest street-pole.

DISCUSSION.

Prof. W. BROWN (*Chairman*), in declaring the Paper open for discussion, drew attention to the statement of the author regarding the necessity of keeping the air gap of the solenoids as short as possible, and mentioned that an air gap of only 0·6 mm. reduced the pull of the solenoid to one-quarter, hence it had been necessary to design the mechanical details of the contrivance that wear of the moving parts did not unduly increase the air gap.

Mr. A. E. PORTE said that what struck him particularly was the great labour, thought, and energy Mr. Tierney had displayed, and the notable difference in design which existed between the newest type of apparatus and the pioneer apparatus described, and spoke of some attempts of his own in the same direction.

Mr. R. N. TWEEDY (Messrs. W. Coates and Son), asked whether Mr. Tierney had experienced trouble due to the burning out of the solenoid coils, as he had heard that with a somewhat similar apparatus considerable trouble had been experienced. He also pointed out that the current taken by the series coil depended upon the motor-man's operation of his controller, as the series coil took the whole current used by the car. Mr. Tweedy also questioned whether the use of "kicking lamps" was really necessary, with so small a shunt coil.

Mr. MARK RUDDLE (City Electrical Engineer, Dublin), asked what was the amount of copper used in the construction of the coils, and the current required to operate the point shifters. He had tried to design solenoids to exert a given mechanical effort with a small current, but had found it to be a difficult matter.

Mr. G. F. PILDITCH (Chief Electrical Engineer, Rathmines) asked whether there was any risk of the point becoming jambed owing to an accumulation of dirt or small stones, also what pressure was necessary to shift a point.

Mr. W. TATLOW (Trinity College) asked whether the current used on the car for lighting or heating purposes affected the working of the series coil.

Mr. J. P. TIERNEY (in reply) explained that both the shunt and series magnets exerted exactly the same power. The pull of each magnet equalled 400 lbs. through a ¾-in. air gap; the current taken by the shunt coil was 1·25 amperes at 500 volts, and that the coils were wound with 35-40,000 turns. The series coil was designed to work at 12 amperes, but of course the current might be more or less, according to circumstances. The drivers had instructions to keep their controller on the first notch when passing points. The only difficulty they had had was to get the drivers to go slow enough, the contact strip was only 18 inches long, and if they passed over it too quickly there was very little time to allow the coils to "build up." Regarding durability of the coils, they had 94 in operation, and had never had one burn out, but the coils were never excited for more than one second at a time, and the average time was only two-fifths second. No difficulty had been experienced due to points sticking; a regular staff of point cleaners was employed who kept all in good order. A point required only 60 lbs. pressure to operate it, whereas the electrical point shifter was designed to exert a maximum pressure of 400 lbs. The lighting current as a rule was insufficient to affect the series coil, but they had had difficulty in one case, in which small cars were used, and 25 lamps were used on each car. They, however, easily got over the difficulty by shunting the series coil. Regarding the necessity of the "kicking lamps," shown on the diagram, the makers would not guarantee that the coils would not break down unless these were used, which he thought was ample reason for using them.

SHIPS' TELEGRAPHS

IN a Paper read before the Institute of Marine Engineers on Monday, December 6th, Mr. J. M. Newall described some electrical systems for affording communication between the engine-room and the bridge of ships, and for warning the navigating officer if his orders have not been properly carried out. Most ships' telegraphs are mechanically operated as regards the transmission of the order, but in some cases electric bells or indicators are provided so that the engineer may acknowledge the order. In the British Navy, single-stroke gongs are used, a push being fitted in the engine-room, and a gong at each transmitting station. In a system developed by Messrs. Chadburn, Ltd., and largely adopted in the Japanese and Italian navies, there is an instrument in the engine-room with a dial similar to that of the transmitting instrument. Bell pushes are put on the sectors corresponding to each order, and the engine-room assistant acknowledges an order by pressing the particular push. This causes an indicator on the dial of the transmitting instrument to appear at the corresponding sector, and a bell is rung simultaneously. Another system developed by the author comprises a device operated from the engine shaft and arranged to warn both the engineer and the navigating officer if the movement of the engines does not correspond with the order signalled. Directly an order is carried out, this is notified on the transmitting dial, but should an order be misunderstood, the dial immediately indicates this and bells are rung, both on the bridge and in the engine room. There is also a recording instrument attached to the telegraph to place on record every order and how each order is carried out. The records of such an instrument would, the author concludes, be of considerable value in disputes before the Admiralty and other Courts as to the carrying out of orders.

A Telephone Repeater.—According to the *Electrical World* (New York), an American patent has been granted to Mr. N. G. Warth for an improved telephone repeater. A horseshoe magnet covers the receiving coils. The poles of these latter are bevelled to conform to the bevel of the armature, and a small block is mounted directly upon the mica diaphragm of the transmitter. This cuts down the moving parts to a minimum. The rear wall of the microphone button is re-entrant, to afford a better disposition of the granules. The air-gap of the magnetic circuit is adjustable through a spacing screw in the transmitter mounting, and the permanent magnet is provided with an adjustable magnetic shunt block for deflecting the polarising field from the air-gap. These adjustments provide for the accomplishment of maximum efficiency of action.

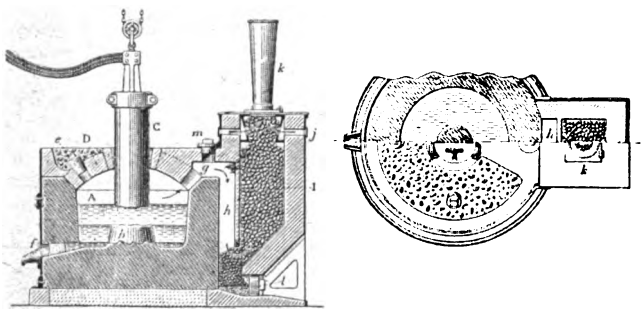
ELECTROMETALLURGY AND ELECTROCHEMISTRY



ACCORDING to *Electrochemical and Metallurgical Industry* of November, important progress has been made in electric zinc smelting. In the retort furnaces usually employed in the smelting of zinc, the thermal efficiency is extremely low, only about 10 to 12 per cent. of the heat units set free by the combustion being utilised. In a closed electric furnace it is, however, feasible to utilise from 45 to 50 per cent. of the electrically produced heat. One ton of coal sets free about 6,500,000 calories on combustion, but only about 700,000 are usefully utilised in the retort furnace. On the other hand, the same thermal effect can be produced by an expenditure of 1,500,000 calories, which is equivalent to 95 to 100 h.p. days. Experiment confirms these figures. Under the most favourable conditions the Belgian and Silesian retort furnaces require per 1,000 kg. of zinc, obtained from 45 to 50 per cent. ores, 2·5 tons of coal, but according to recent tests, one ton of zinc can be extracted from the same ore by the expenditure of electrical energy equivalent to 2,500 h.p. days. The electrical h.p. year will cost about 50s. to 56s., that is, presuming the cost to be the same as the coal in the retort furnaces. Of course, in mountainous districts with easily available water power, the cost may be lower than this. These figures show that electric zinc smelting is in a more advantageous position than the electric reduction of iron ores. Another important point is the wages item, which can be considerably reduced in the electric furnace. There is also in the retort process a very heavy outlay in connection with the clay retorts. At the present stage of the work, however, it is rather difficult to compare the relative structural expenses of the two processes.

The Côte-Pierron process has particular features of interest, both in connection with the reduction of the zinc ore and the condensation of the zinc vapour. In order to reduce the sulphide and dispense with the usual roasting process, the ore is mixed with iron, which, at the high temperature of the electric furnace, readily reduces it with formation of iron sulphide.

$$ZnS + Fe = Zn + FeS.$$

The zinc vapour, however, owing to the gangue containing a certain amount of moisture and carbonates, is contaminated with certain quantities of water vapour and carbon-dioxide, and also unavoidable traces of air. These impurities cause the formation of zinc mist, that is, a portion of the zinc becomes oxidised, and this interferes with proper condensation. In order to get over this difficulty, the vapour is passed up a column of carbon heated to a low red temperature. This temperature is sufficiently high to cause reduction, but is not high enough to prevent condensation. Another important point in connection with the iron reduction, is that lead is removed. The lead sulphide present in the ore is reduced at a lower temperature than the zinc sulphide, consequently the lead can be tapped off first.

Vertical and horizontal sections of the furnace are given below. *A* is the crucible, the lower part and sides of which

SECTIONS OF CÔTE AND PIERRON ZINC FURNACE.

are of graphite encased by sheet metal, and connected with one pole of the electric circuit. The other pole is connected to the vertical electrode *C*, the lower end being above the projection *b* in the bottom of the crucible, so that current can be caused to flow between these two points. The roof *D* is of refractory brick.

The zinc vapours on leaving the furnace pass through *g* and down the channel *h* to the condenser *l*, which is a vertical chamber having refractory walls, and is filled with broken carbon kept at a low red heat. The tapping hole of the condenser is at *l*. The downward passage of the carbon in the condenser is at such a speed that the temperature is maintained at a sufficiently high standard to reduce the zinc mist, and allow the condensation of the zinc. The opening, *m*, is provided for cleaning the channels *g* and *h*, should clogging take place. The charge is placed on the furnace top *D*, where it becomes dried before charging in at *e*. Before the charge is inserted the electrode *C* is brought into contact with *b*, so that when the charge is introduced the current passes through it only. The heating is thus simply by contact, and the temperature so produced is sufficient to cause the lead sulphide to reduce. The molten lead flows to the bottom of the furnace, and is tapped off at *f*, which is kept open. When the lead has ceased to flow from *f*, this tapping hole is closed and also the tap hole *l*. The electrode *C* is now gradually raised, and the charge becomes heated by arcing and resistance, and a very much higher temperature is obtained; this causes reduction of the zinc sulphide, and finally the temperature is raised sufficiently high to cause volatilisation. When the zinc vapour passes into the condenser it is at a temperature of 1,200° to 1,300° C. It is consequently necessary to have a large condensing surface, and this is obtained by the large quantity of broken carbon. The liquid zinc, as it trickles down over the condensing surface, collects behind the door at *l*, and is tapped off from time to time.

The first experiments were made by Messrs. Côte and Pierron in 1906 at Lyon with a 100-h.p. furnace. The work was first taken up to obtain the best conditions for condensation of zinc in liquid form and for the production of zinc oxide (zinc white). For the preparation of zinc white they find it better not to use the iron bath for reduction, because small quantities of iron volatilise and contaminate the white. They therefore reduce with a mixture of lime and carbon, according to the following equation :—

$$ZnS + CaO + C = Zn + CO + CaS.$$

From zinc ore containing theoretically 13,193 kg. of zinc oxide they obtained, in 600 hours, 12,370 kg. This new zinc and zinc white process certainly seems to have a promising future.

According to the *Revue d'électrochimie et d'électrométallurgie*, ozone prepared by the action of the electric discharge upon the air contains oxides of nitrogen, and M. Bonjeau has noticed the action of these oxides upon lead pipes which have been used to convey the ozone in water-purification works. The result has been that nitrate of lead has been found to contaminate the water—naturally a very serious matter. He therefore suggests that metallic pipes should never be employed to convey ozone from the ozonisers to the sterilising plant. Probably the production of ozone is due to sparking in the ozonisers, because a perfectly silent discharge is usually supposed not to cause oxidation of atmospheric nitrogen. According to the same journal (*loc. cit.*), the town of Chartres, in France, is now having the drinking water obtained from the River Eure purified by means of ozone. The water contains in the first place from 3,000 to 16,000 bacteria per cubic centimetre, but treating with 2 grm. of ozone per cubic metre of water, it is practically bacteria free. The installation used is the high-tension system of Otto, which is worked in duplicate, each part being capable of sterilising 6,000 (211,800 cubic feet) cubic metres of water per 24 hours. A 40-h.p. steam engine raises the water a height of 11 metres (35·7 ft.), and drives an alternator giving 500 periods at 250 volts; this is then transformed up to 20,000 volts. The ozonisers consist of glass plates as dielectrics which have tin foil between them, and the air is passed between the plates. Fifty watts are required to produce 2 grm. ozone, and as this is sufficient to sterilise 1 cubic metre of water, 12 kilowatts are required for the 24 hours. A project is also on foot to sterilise Paris water in a similar manner, when it is hoped it will be possible to set up plant which will be capable of sterilising 1 cubic metre of water with an energy consumption of 10 watt-hours.

The Langbein-Pfanhauser-Werke Aktiengesellschaft of Leipzig have recently produced, commercially, iron plates, sheets, and other articles electrolytically, the iron having a purity of 99·95 per cent. [*Zeitschrift für Elektrochemie*, 15 (1909), 595] The process employed is that of F. Fischer, the iron being obtained by electrolytic means direct from the bath, ordinary cast-iron being employed as anode. The iron, being of such a high state of purity, is very soft and ductile, and for electrical purposes, for example for transformer plates, should be of great value. Before annealing its hardness is 92 and after 62. With the same scale (Brinell's method) the hardness of steel is 300 to 500, of annealed copper 95, gold 97, silver 91, and aluminium 52, When $\frac{1}{8}$ in. plates are rolled out the hardness rises to 175, but on re-annealing becomes again 60-62. Naturally the product can easily be worked, and may be cut with a knife, is readily welded, and can be hammered out cold. An important property is that articles shaped in the soft material can be hardened in parts or throughout by causing it to take up carbon by any of the usual hardening methods. At present the firm manufacture plates of from $\frac{1}{25}$ in. to $\frac{3}{8}$ in. It is claimed that these plates are particularly well adapted for the preparation of stereotypes, as the front may be hardened while the ductility of the back is retained. It has also been found feasible to make thin, seamless tubes up to 1 in. in diameter. It is expected that in a short time the manufactory will be producing articles of all shapes and sizes, at prices which will enable them to compete with similar articles made by present methods. One very interesting thing which they manufacture is armoured lead pipe of 1 in. in diameter, which has an iron coating of 1 mm. in thickness.

ELECTRICALLY-DRIVEN RAILWAY TURNTABLES

SOME electrically-driven turntables have recently been constructed and erected in the locomotive sheds and yards of the German and Austrian State railways. Among these is that installed by the Vereinigten Elektrizitäts Akt.-Ges. of Vienna in the Attnang-Puchheim station yard, and described recently in the *Elektrotechnische Zeitschrift*.

This turntable, illustrated below, has a diameter of 18 metres (59 ft.), and rotates at a speed of one revolution per minute. It was designed for a maximum load of 125 tons. As indicated in the plan of Fig. 3, the turntable is hauled round by a small electric locomotive, coupled to it by means of the pin *B*, shown in Fig. 1. The locomotive comprises a heavy

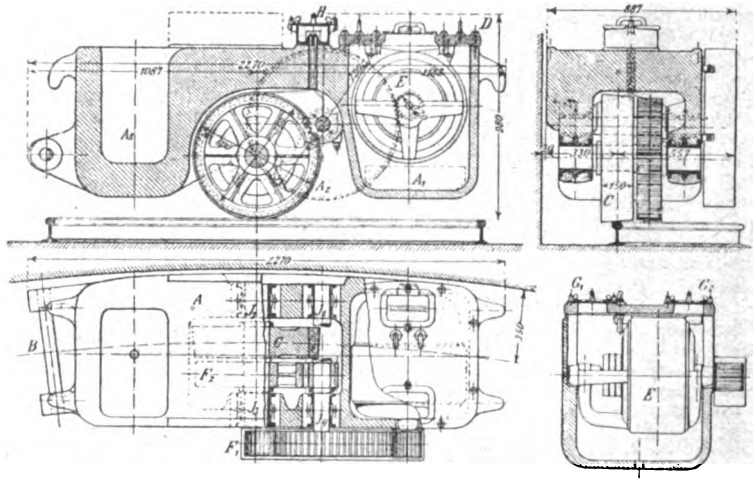

FIG. 1.—LOCOMOTIVE FOR HAULING TURNTABLE.
(Dimensions in millimetres.)

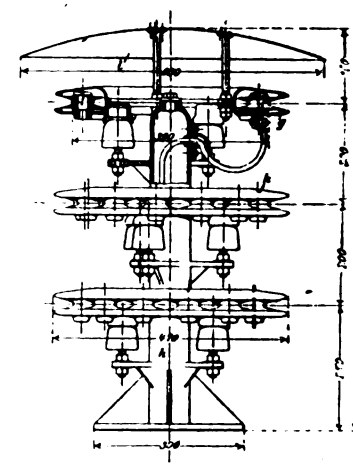

FIG. 2.—THREE-PHASE ROLLER COLLECTOR.
(Dimensions in millimetres.)

casting divided into three compartments, A_1, A_2, and A_3, and has only one wheel *C*, which runs on the rail in the pit. In the fore compartment, A_1 is the motor, which is hung from the covering plate *D*. The motor *E* is a 220-volt 48-cycle three-phase slip-ring motor rated at 9 h.p. with intermittent load, and runs at a speed of 690 r.p.m. It is coupled to the wheel *D* through a double-reduction spur gearing, F_1, F_2. To render the motor slip-rings and bearings accessible, two hand-holes G_1, G_2, are provided in the cover. The total weight of the locomotive is 4·4 tons, and the parts are arranged so that the whole is effective

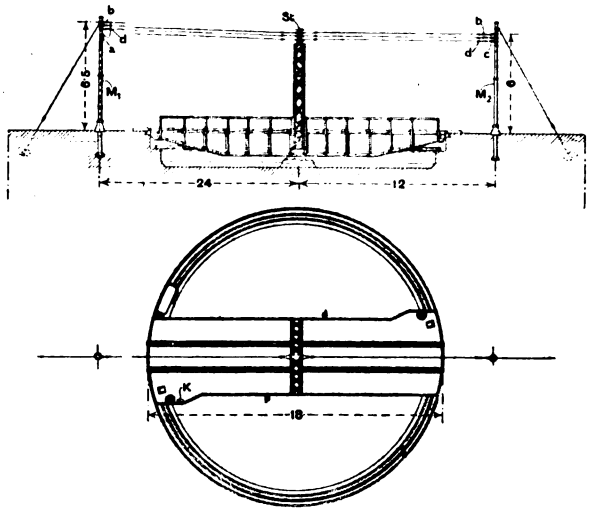

FIG. 3.—PLAN AND ELEVATION OF ELECTRICALLY-DRIVEN TURNTABLE.
(Dimensions in metres.)

in producing adhesion. If necessary, the weight can be increased by placing heavy masses in the compartment A_3 or on the top of the locomotive. Oil for the lubrication of the bearings J_1, J_2, J_3, J_4 is supplied from the box *H*.

Current is supplied to the motor from three contact wires stretched 6·5 metres above the turntable, by means of a collector *St* fixed on a steel tower in the centre of the turntable. On account of local conditions, the supporting poles M_1, M_2 had to be placed at unequal distances from the centre of the turntable. The contact wires are 8 mm. diam. silicon-bronze wires stretched in a vertical plane at distances of 200 mm. apart, and they are attached to the poles by means of strain insulators and turn-buckles *b*. In order to take up the variation in length due to temperature fluctuations, springs are introduced in the wires as shown at *c*. The cables supplying the current are carried up the hollow pole M_1 to a water-tight terminal box *a*, from which connections are made to the three wires as shown at *d*. Above the centre of the turntable, each wire is formed into a loop, the two sides of which are in contact with the collector rollers.

The collector, illustrated in Fig. 2, comprises three sets of twelve contact rollers *e*, which rotate on pins attached to annular metal supports fixed on insulators. Each support has a cover *k*, and another cover *l* is fixed above the whole. The insulators are supported on brackets extending from the cast-iron pillar which is fixed to the top of the steel erection in the centre of the turntable. An armoured three-core cable conveys the current from the collector to the locomotive. The reversing controller for working the locomotive is fixed on the turntable as shown at *K* in Fig. 3. A similar turntable is to be installed shortly in Mannheim.

Music Over Telephone Lines.—A novel form of service has been introduced at the telephone exchange at an American town named Wilmington, in Delaware. According to *Telephony* (Chicago), when a subscriber wishes to be entertained he rings up the exchange and gives the number of the piece he desires, when the corresponding record is placed in a phonograph at the exchange and the instrument connected to his line. A special receiver is used provided with a megaphone.

"Electric Ignition."—In a lecture given before the Glasgow Scientific Society, on December 18th, Professor Magnus McLean separated methods of ignition into two groups, viz., low-tension and high-tension, and showed how the E.M.F. necessary to spark across the air-gap varied with the compression. He drew attention to the effect the relative sizes of capacity of condenser and the inductance of coils have on one another in producing the most effective spark in firing, and described the various principles of high-tension ignition as applied to four-cylinder engines. He described the four-coil method with separate trembler, the use of four coils with one trembler, and the arrangement using one coil with a high-tension distributor. Illustrations were also given of the well-known Lodge "B" spark method, which was shown experimentally by apparatus on the lecture table. The Eisemann system was next described. In this arrangement the secondary or firing spark takes place when a sudden rush of current goes through the primary coil. This is contrary to what takes place in an ordinary inductance coil, where the spark occurs in the secondary when the primary is broken, and not when it is made. An experiment was shown illustrating how the spark on "make" instead of on "break" is produced, and a full and lucid explanation given. Professor McLean then turned to low-tension systems, and gave illustrations and diagrams of (1) a rotating armature giving two sparks per revolution; (2) a rotating sleeve giving four sparks per revolution; and (3) a rotating magnet. Some particulars were given of one magneto on the latter system, in which it appeared the energy of each spark was a third of a joule, or a quarter of a foot pound. In the particular car referred to, the magneto rotates at 950 r.p.m. with the car running at twenty-three miles per hour; thus the h.p. necessary to give spark at this speed is about one-seventieth. An interesting discussion followed.

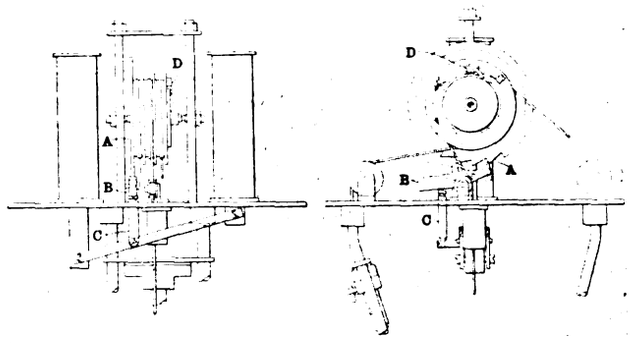
AN ARC LAMP PATENT DISPUTE



ON December 13th last, opposition was entered at the Patent Office by Mr. H. P. Bleckley, of the Abbey Electric Co., to the grant of a patent to Mr. C. E. G. Gilbert, of the Gilbert Arc Lamp Co., Ltd., for a feeding mechanism for arc lamps. Mr. Bleckley alleges that the invention is covered by a previous patent, No. 521 of Jan. 8th, 1907, granted to E. Pearce and S. Walton, and that the nature of Mr. Gilbert's invention and the manner in which it is to be performed is not sufficiently or fairly described and ascertained in the complete specification.

The patent in question is No. 27,303 of December 16th, 1908, by C. E. G. Gilbert, of Chingford. The complete specification was accepted on October 7th, 1909, and a brief abstract appeared in ELECTRICAL ENGINEERING, November 4th, page 950. The specification and drawings refer to an improved feeding mechanism for arc lamps, consisting of a drum revolved by the weight of the carbon-holders without any clockwork. The drum is connected with a toothed wheel, and its rotation is controlled by two independent pawls operated by the rocking lever, which is in turn controlled, as usual, by the shunt and series solenoids. The parts are so arranged that only one pawl engages the toothed wheel at a time. The exact manner in which the pawls act, and also the means and reasons for a total disengagement of both pawls, were fully explained in the illustrated description of the lamp (the "Beacon" flame arc lamp) which appeared on page 1055 of ELECTRICAL ENGINEERING, December 16th, 1909.

The claims of the patent are as follows:—

1. In an arc lamp, the control of the "feed" by means of a toothed wheel and two independent pawls allowing a tooth by tooth "feed" in the manner set forth.
2. The final total disengagement of both pawls as described.
3. The improved feeding mechanism for arc lamps substantially as described.

The patent advanced as an anticipation of the Gilbert patent is No. 521 of 1907. This was granted to E. Pearce, of London, and S. Walton, of Charlton, and describes a mechanism in which the carbons are fed down by the weight of the carbon-holders, and the feeding regulated by the solenoids acting through a rocking lever controlling the rotation of the drum around which pass the cords connected to the carbon-holders. The drum, as shown in the accompanying figure, has three grooves, and is loosely mounted on a spindle to which is fixed a large ratchet wheel *A* and also a smaller one. The latter engages with a riding click *D* mounted on the drum so that the drum can move relatively to the ratchet wheels only in the direction in which the carbons are wound up, as shown by the arrow in the figure, which is reproduced from the specification. Engaging in the teeth of the large ratchet wheel *A* is a double-toothed rocking click *B* pivoted to the frame. This click is caused by a spring to remain normally in the position in which the right-hand tooth engages the wheel, but is rocked by the pin *C*, which is pivoted to the rocking lever. This occurs when the arc becomes long, and causes the right-hand tooth to release the ratchet wheel *A*, but before the latter can move through a distance of more than one tooth, the left-hand tooth of the click engages with the wheel as shown by the dotted lines in the figure, and holds it. The carbons now being fed, the series-coil tilts the rocking lever back and allows the click to resume its normal position with the right-hand tooth holding the wheel. The carbon-holders are wound up by pulling the cord provided.

FEEDING MECHANISM DESCRIBED IN THE PEARCE AND WALTON SPECIFICATION.

The claims of this patent are as follows:—

1. In an inclined carbon arc lamp a double-toothed rocking click and ratchet wheel or their equivalents for the purpose set forth.
2. In an inclined carbon arc lamp the combination of a double toothed rocking click and ratchet wheel or their equivalents and means, actuated by the rocking lever of the lamp, for actuating the said click or its equivalent for the purpose set forth.
3. In an inclined carbon arc lamp the combination of a double toothed rocking click or its equivalent, a ratchet wheel or its equivalent mounted fast on a spindle, a pulley mounted loose on the spindle, a subsidiary ratchet wheel mounted fast on the spindle, a click mounted on the pulley and engaging the subsidiary ratchet wheel, and means actuated by the rocking lever of the lamp to actuate the double-toothed click substantially as set forth.
4. The arrangement and combination of parts substantially as set forth.

A NEW FREQUENCY CHANGER

AN interesting form of frequency changer, suitable for connecting together two A.-C. supply systems of different frequencies, or for supplying a common system of mains from both systems, is described in a patent specification, No. 26,198 of Dec. 4th, 1908, by the Lancashire Dynamo & Motor Co., Ltd., and Messrs. A. P. Wood and R. S. McLeod. The specification has been accepted, and was published on Thursday last.

It is pointed out in the specification that, according to existing practice, a frequency changer comprises two alternators, the rotors of which are mechanically coupled together; one of these machines is connected to the mains of the one supply and the other is connected to the mains of the other supply and to the common system of mains. Whilst the rotors run at the same speed, the frequencies of the machines correspond with the frequencies of the respective supplies. This arrangement presents difficulties in starting up and synchronising, and as any tendency of either station to depart from its normal frequency has to be prevented by the coupled alternators which link the supplies together, it will be seen that when each of the coupled supply stations has an output which is large as compared with that portion which is supplied to the common mains, the tendency of either to depart from normal frequency can only be resisted by the coupled alternators transmitting a very considerable torque which may exceed that which can be safely transmitted. With this arrangement, the ratio of the frequencies must be maintained exactly at that for which the two supply systems are designed, and this in practice is difficult of attainment.

The object of the present invention is to provide an arrangement in which the torque transmitted may be automatically regulated so as not to exceed a predetermined maximum, and so that a considerable departure of either of the coupled stations from its normal frequency is permitted. Two alternators are provided, the rotors of which are mechanically coupled together. The stator of one of the machines, referred to in the following as the case, is made rotatable about the axis of the rotor, and its rotation is controlled by gearing it to a motor which applies to it a torque varying in sign, but not exceeding a predetermined maximum. Denoting the machine with the rotating case by *A*, and the other by *B*, the speed of the rotors will be that corresponding with the frequency of the supply to which *B* is connected, and if the frequency of the other supply corresponds with this speed and the number of poles of *A*, the case of the latter will remain stationary, and will be held stationary by the case-controlling motor. Should the frequency of either supply change, the effect will be to tend to alter the torque between the case and the rotor of *A*, and as the case motor is arranged to exert an approximately constant torque, the case will rotate in one direction or the other, in accordance with the relative effect of the change of frequency, and by so rotating it will accommodate the frequency changer to the altered ratio of the frequencies.

The case-rotating motor may be connected to either supply, or it may be a D.-C. motor, and it would be so connected to resistances as to provide a practically constant torque between its stator and rotor, whether the latter is stationary or not. When the motor is driving the case its energy will be transferred to the system, and this may also be arranged to take place when the case is driving the motor. One mode by which this result may be accomplished consists in providing a small motor-generator set in addition to the case-controlling motor, which latter would be in this case a D.-C. motor supplied with current from the generator of the motor-generator and having a separ-

Digitized by Google

ately excited field; the motor part of the motor-generator may be D.-C. or A.-C.; the generator side is D.-C. and is wound after the manner of the automatic revisible booster described in the Specification to Patent No. 14,373 of 1902; that is to say, it has a self-exciting winding, a shunt winding, and a series winding, the latter being arranged to have a heavy back-compounding effect. With this arrangement the generator would work at any current for which it was set, and would automatically vary its voltage for the case-controlling motor accordingly as the latter was stationary or running in either direction; under these circumstances the case-controlling motor would exert a constant torque, and energy approximately constant in amount would be transferred by the frequency changer independent of variations in frequency or voltage.

When the ratio of the frequencies of the two supplies cannot be expressed by two numbers suitable for the numbers of the poles in the respective alternators, a frequency changer as described can be employed with a constantly running case.

THE FLICKER PHOTOMETER

A PAPER by Mr. H. Morris-Airey on the use of the flicker photometer for differently coloured lights was read on Monday, December 13th, before the Newcastle Local Section of the Institution of Electrical Engineers.

From time to time suspicions have been raised as to whether the principle on which flicker photometers are based does not involve physiological phenomena which disturb the conditions so that the numbers obtained are not a true representation of the illuminating powers of the sources to be compared. The exact *rôle* which the speed of rotation of the flicker head plays in the experiment is especially doubtful. The problem as to what actually happens in the retina when it is stimulated by steady or intermittent light is entirely a physiological one. Ordinary theories of three-colour vision do not account for certain marked differences which have been observed in the rate of growth and decay of the retinal stimulus due to differently coloured lights. G. N. Stewart found that on observing the flashes of light reflected from a rotating mirror placed in a darkened room, a series of colour changes in the appearance of the image of the source took place as the speed of the mirror was altered. These changes take place at or under the speed necessary for the complete steady fusion of the flashes. He plotted curves representing the growth of the stimulus for red, green, and violet light, which showed that for a white light stimulus of long duration the excitation of all three colours is equal, giving the sensation of white light. For stimuli of shorter duration, the violet, green, and red excitations are predominant in turn, according to the duration of the flashes. The succession of colours in "after-images" is consistent with the assumption that the decay of the excitation follows a similar set of curves. As these colours are observed with intermittent light when the frequency is about or under that required for complete fusion (*i.e.*, disappearance of the flicker), it seems difficult to avoid the conclusion that they will play an important part in the appearance of a flicker photometer head when using for comparing different colours. Suppose we have adjusted the sources and speed of rotation so that the flicker has just disappeared and we have a balance. The flashes from either source considered independently evidently occur at a rate such that the excitation is not fully developed.

In view of these facts, the author considers that the conditions under which the retina is excited during a measurement with the flicker type of photometer are not the practical conditions of illumination to which it is our object to apply the data we obtain from the experiment.

Mr. Morris-Airey expanded his Paper by an exposition of Talbot's law, which for many years was regarded as the basis of flicker photometry, that the impression on the retina due to interrupted beams of light was, over the time considered, equal to that of the same total quantity of light if it had been continuously applied. This law was experimentally found to be true within 0·5 per cent. for white light, but doubt was expressed that it could be true for changes between two lights of different colours. Moreover, it was noticed that the frequency at which fusion or blending of the impressions occurred varied considerably with the intensity of illumination. Mr. Airey demonstrated, by means of the Benham top and other apparatus, the difficulty of relying upon optical demonstration of relative colour values and light intensities.

DISCUSSION.

Professor STROUD, who was chairman of the meeting, said that the probable conclusion to which one would have to come, after the reading of this Paper, was that flicker photometry was only precise when lights of the same type were being considered.

Professor THORNTON said that as regards the time effect of the ray upon the retina, the flicker photometer appeared to intensify the defect which it was designed to overcome. The great advantage of the flicker photometer was, however, its extreme sensitiveness as compared with fixed photometry. Mr. Airey had shown conclusively that error existed; it would be interesting to know the order of that error. It might be worth while mentioning that in some recent experiments at that college, some metal filament lamps had been balanced as perfectly as possible by eye-photometry, but when the balance was checked by photographic plates there was a very considerable lack of balance.

Mr. J. H. HOLMES also wished for more quantitative information, and emphasised the importance of being able to assign photometric values to coloured lights such as those of flame arc lamps.

Mr. FARADAY PROCTOR said that in the practical manufacture of lamps it was difficult to get anything like consistency in the photometric testing of metallic filament lamps. Girls in the photometric testing rooms, who were able to check the ordinary carbon filament lamps with great accuracy, when given metal filament lamps to test, could obtain no agreement among themselves. This pointed to the fact that when one changed the personality of the tester one obtained very different results, and it took a good deal to get girls sufficiently educated up to metallic filament photometry to get sound results.

Mr. MORRIS-AIREY, in reply, said that as to the magnitude of error involved, the best answer was probably that it was doubtful if an absolute comparison of very differently coloured lights was possible. It was, indeed, doubtful whether one could really talk of comparing the intensities of such lights. As regards the difference of result, however, between measurements made by the flicker and the steady types of photometer, it was possible to get an error up to a maximum of about 25 per cent. when comparing different sources of light, such as a metal filament and a carbon filament lamp. By keeping the flicker wheel at rest in a Simmance and Abady photometer in a certain position, it was possible to use it as a steady photometer, and when this was done, and afterwards the same instrument was used as a flicker, the difference in the comparisons went, he believed, against the metal filament lamp. The photographic plate was even more deceptive than the eye. In reply to Mr. Holmes, the time required for stimulating the retina to full excitation varied from $\frac{1}{10}$th second with bright lights to $\frac{1}{11}$th second with faint lights.

ACCUMULATOR LOCOMOTIVE WITH EDISON CELLS

A 20-TON accumulator locomotive, carrying a battery of 408 Edison cells, has been in service for some months on a local line between Elbing and Braunsberg in Königsberg, East Prussia. This locomotive has been constructed chiefly for experimental purposes by the firm of F. Schichau, and is described in a recent issue of the *Elektrotechnische Zeitschrift*.

The length of the locomotive over the buffers is 25·6 feet, and the cells are arranged in the usual manner on each side of the cab in water-tight chambers, with ventilating openings provided with dust filters. The battery comprises 408 Edison cells of the H. 45 pattern, with a capacity of 280 amp.-hours each, so that the average discharge pressure is 502 volts. The cells are grouped in wooden crates in batches of four. Each cell measures 6·7 in. by 5 in. by 12·2 in. high, and the total weight of the battery, including the wooden crates, is 5·9 tons, or about 32 lbs. per cell. As is well known, the perforated nickel pockets of the positive plates contain nickel oxide, and those of the negative plates iron oxide. The plates themselves are of nickelled iron, and there are twice as many positive as negative plates. The plates are spaced only 1·5 mm. apart, and are separated by thin rectangular hard-rubber sticks. Hard-rubber pieces insulate the plates from the containing case, and the terminals from the cover, which is sealed on. The electrolyte is a 21 per cent. solution of caustic-potash, which covers the plates entirely. The life of both positive and negative plates is said to be over 93,000 train-miles. The electrical equipment of the locomotive comprises two series motors, each with a capacity of 35 h.p. on the one-hour rating, and coupled to the driving axles through single reduction gearing of 1 to 4·44. The motors have series-parallel control, there being five series, four parallel, and one short-circuit braking positions of the controller. On account of the low supply pressure available, the battery is charged in two parts, the cost of a single charge with current at 6 pf. per unit being 18 marks. The total weight of the locomotive is 19·5 tons, made up of 9·8 tons for the body, frame, and trucks, 3·8 tons for the motors and switch-gear, and 5·9 tons for the battery. On the test run, this locomotive hauled a loaded goods truck with a total weight of 36 tons over a distance of 132 miles on one charge, which had lasted $3\frac{3}{4}$ hours. At the end of the journey, the battery had a terminal pressure of 468 volts, so that it would have been possible to run another 30 miles. The cells are said to have given every satisfaction, both during charge and discharge.

CATALOGUES AND PAMPHLETS, &c., RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

CALENDARS, POCKET BOOKS, &c.—We have received a useful pocket book and almanac of conveniently small size, bound in morocco, from the Electric Construction Co., Ltd. (London and Wolverhampton), accompanied by a nickel-plated pocket knife.

One of the neatest desk calendars issued this Christmas is that of the Central London Railway, with roller arrangement, enabling the different months to be brought before the opening as required.

The Christmas greetings of Messrs. Wellman, Seaver & Head's electrical department (47 Victoria Street, S.W.) are accompanied by a neat case containing a double pack of patience cards.

Messrs. J. Spencer, Ltd. (Wednesbury), are sending out with their list mentioned below an aluminium continuous pocket calendar up to the year 1927, about the size of a half-crown.

A very convenient small pocket case is being issued by Messrs. W. F. Dennis & Co. (49 Queen Victoria Street, E.C.), containing a calendar and a booklet of useful data and tables relating to wire of all kinds.

The Chloride Electrical Storage Co. (Pendlebury, Manchester) are issuing their convenient daily tear-off calendar, which gives on each sheet not only the day of the month and week, but a calendar of the previous, current, and next month.

CURATIVE APPLICATIONS OF ROENTGEN RAYS.—A leaflet from Messrs. Siemens Brothers & Co., Ltd. (Caxton House, Westminster, S.W.), describes apparatus designed for applications of Roentgen irradiations in certain gynæcological cases, in the form of a reprint of an article on this subject.

IRON TUBES, &c.—A new leaflet from Messrs. John Spencer, Ltd. (Wednesbury), gives prices of standard sizes of wrought iron pipes and fittings, with particulars of boiler tubes, steel steam piping, and illustrations of other specialities of the firm, including tramway and telegraph poles, &c.

ARC LAMPS.—A leaflet from the Allgemeine Elektricitäts-Ges., of Berlin, gives particulars of some new designs of flame arc lamps with vertically arranged carbons. These give a maximum illumination at an angle of about 30° below the horizontal, and are thus especially adapted for street lighting.

TURBINE-DRIVEN AUXILIARIES.—The Allgemeine Elektricitäts-Ges., of Berlin, have sent us a well-illustrated *brochure* describing the construction of turbine-driven auxiliaries and their application to generating and other steam turbine plants. Photographs and drawings of the sets described in Prof. Kapp's recent Presidential address to the Institution of Electrical Engineers are given, and other illustrations of turbine-driven air and cooling-water pumps, combined pumps for condensing plant, feed-water pumps, and other centrifugal apparatus are also given, together with performance curves, dimensions, and detail descriptions of the apparatus.

AUTOMATIC TRANSFORMER SWITCH.—Mr. G. Braulik (8 Lambeth Hill, Queen Victoria Street, E.C.) has sent us a leaflet calling attention to a new automatic transformer switch which he is placing on the market in this country.

ARC LAMPS FOR INDIRECT LIGHTING.—A leaflet from the Electrical Co., Ltd. (122 Charing Cross Road, London, W.C.), gives particulars and prices of a number of different patterns of arc lamps for indirect lighting. The covers and reflectors have been designed by Professor Behrens, and are artistically finished in light green lacquer relieved with gold bands. Lamps taking from 6 to 20 amps, both A.-C. and D.-C., and with from 10 to 16 burning-hours, and some long-burning (from 22 to 100 hours) enclosed D.-C. lamps are listed. Carbons, resistances, and other accessories are also included.

CORRESPONDENCE

BATTERY CONTRACTS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Our attention has been called to a note in the column of "Tenders Received and Accepted" of your last issue, in which, among many others, one for Manchester Corporation is mentioned. As it is possible that your readers may confuse this with the large battery which, as is well known, is being put down by the Manchester Corporation Electricity Department, we wish to state that the battery referred to in the note is for Manchester Corporation Waterworks Department, and has only a capacity of about 60 kw. for one hour. The Electricity Works battery, which is the largest single battery in this country, will be a Tudor battery, and will have a capacity of about 3,200 kw. for one hour.

We are, Sir,

Your obedient servants,

119 Victoria Street.
December 28, 1909.

THE TUDOR ACCUMULATOR CO., LTD.

THE ELBE TUNNEL AT HAMBURG

Electric Lifts for Road Vehicles

A TUNNEL for pedestrians and vehicular traffic, which will be connected with the surface at each end by electric lifts, is now being constructed under the River Elbe at Hamburg. It is expected that the tunnel and the shafts on either side of the river will be completed next summer, which would permit of the opening to public service in the following spring. The tunnel itself comprises two steel tubes, about 1,500 ft. long, constructed under the bed of the river, some 52 ft. below high-water level. Each tube has an outer diameter of 19·5 ft., and the distance between the centres of the tubes is 26 ft. The roadways are 6 ft. wide, each with a footway 4 ft. wide on either side. The shafts are 71·5 ft. in diameter, and each contains six electric lifts and two stairways. The two central and largest lifts are designed for a load of 10 tons each, and will take vehicles of the heaviest kind; the two adjacent lifts, each with a capacity of 6 tons, are for medium-sized vehicles, and the other two are passenger lifts, each capable of dealing with a load of 2·3 tons. On special occasions only will the vehicle lifts be used for passenger traffic. The height of travel is 75 ft., and the journey will take 35 seconds in the case of the largest lifts, and 25 seconds in the case of the passenger lifts. Each passenger lift will hold 30 persons, while the two vehicles lifts will accommodate 80 and 135 persons respectively.

All the winding machinery will be situated above the lifts. The latter will be provided with side doors to enable passengers to change from one lift to another in the case of an accident to the gear. Oil buffers will be arranged under each lift to take the shock in the event of the lift not being stopped at the proper level. The lifts will have the usual counter-balance weights, and will be suspended over winding drums. The drums of the vehicle lifts will each be driven through worm-gearing by two motors, and those of the passenger lifts by one motor. Each motor will have three field windings—a shunt field, a series field only in circuit at starting and gradually cut out as the speed increases, and an auxiliary winding for reducing the speed when stopping. The electrically operated controllers will be worked by one of three switches, one at each entrance to the lift, and one in the lift itself. Further, there are contacts at the ends of the shafts and in the door locks to prevent over-winding and starting with the doors open respectively. The lifts are automatically stopped at the proper level in the following manner: At a distance of about 12 ft. from the stopping place a control circuit is broken which causes a resistance to be inserted in the armature circuit, and the auxiliary field winding to be connected with a resistance in series. A second control circuit is broken at a distance of about 6 ft. from the stop, and this puts an electromagnet into circuit which cuts out the resistance in series with the auxiliary field winding according to the value of the load. With a heavy load the retardating effect of the auxiliary winding will be greater, so that the lift will be brought to rest automatically at the proper level, independently of the load. At the end of the travel a third control circuit is broken. This causes current to be cut off from the motors, and the electromagnetic brakes to be applied. In the case of this last device failing, a limit switch just beyond the normal limit of travel is provided to effect the same results. The passenger lifts will be controlled solely by the attendant in the car, but the vehicle lifts may be operated from the platforms. Regenerative control will be provided so that the motors will return energy to the supply network when the lifts are descending loaded.

The tunnel will be lighted electrically by means of incandescent lamps. Two electrically driven high-pressure centrifugal pumps will be used to pump the water out of the sumps up to the town sewer. The above particulars are taken from an abstract of a Paper by E. G. Meyer, read before the Elektrotechnischer Verein, Hamburg, which appeared in a recent issue of the *Elektrotechnische Zeitschrift*.

Embezzlement.—At Bow Street Police Court, last week, Vincent Edward Moir, Secretary of the National Society of Telephone Employees, was charged with embezzling £1 15s.; but as a charge of embezzling £500 is also to be preferred against him, the accused was remanded on bail in two sureties of £150 each.

Pataud and the Electricity Supply of Paris.—According to Paris correspondents of the daily papers, the notorious agitator Pataud planned an elaborate coup for a Christmas surprise for Parisians which was foiled by the forethought of the authorities. Pataud called at the Ministry of the Interior on Christmas Eve and threatened again to place the town in darkness unless his demands were acceded to. To his astonishment he was received by the Premier's chief secretary, and informed that arrangements had been secretly completed whereby the supply could be given if necessary from the generating plant of the Metropolitan Railway, so that cessation of supply from the stations controlled by the Pataud syndicate would not result in placing the city in darkness. The work of interconnection must have been one of no small magnitude.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 23rd, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

22,873/08. **Production of Tantalum.** SIEMENS & HALSKE AKT.-GES. Pure ductile tantalum is produced by reducing a mixture of tantalic acid (or other oxygen compound) and carbon at a white heat in a current of hydrogen. The reduction can be carried out in an electrically-heated carbon tube or an electric current can be passed directly through the mixture pressed into rods. One claim.

26,198/08. **Frequency Changer.** THE LANCASHIRE DYNAMO & MOTOR CO., LTD., A. P. WOOD, and R. S. MCLEOD. A full description of this machine is given on another page of this issue. Four claims, three figures.

26,251-2/08. **Fuses and Resistance Grids.** A. WEST. The first specification describes a porcelain fuse carrier with spring contacts in the hollow extremities (not cemented in). The contact cheeks lie in recesses, and are pressed out by springs on to rigid contacts on the board. The second specification describes resistance grids stamped out of sheet metal with corrugations parallel to the sides of the bars to give them strength, and to prevent change of shape. Three claims, three figures.

26,363/08. **Supplying Oscillatory Circuits.** E. VON LEPEL. The primary oscillation circuit of a wireless or similar plant is charged by means of a rotary contact-maker which connects condensers to the supply and oscillation circuits alternately. The condensers are thus charged, and then discharged into the oscillation circuit in rapid succession. The contact-maker thus takes the place of an interrupter and works sparklessly. The condensers may be in parallel during charging, and in series during discharging in order to apply a high voltage to the oscillation circuit. Four claims.

26,826/08. **Resistance or Heating Elements.** BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*). These are made from an alloy of tellurium and silicon, which has a higher resistance than silicon alone. With 5 per cent. tellurium, the resistance is from three to five times that of silicon, and the alloy is not brittle, but anything from one to fifteen per cent. is employed. Four claims.

Opposition to Grant of Patents

27,303/08. **Arc Lamp Mechanism.** C. E. G. GILBERT. This patent (abstracted in ELECTRICAL ENGINEERING, Nov. 4th, 1909, p. 950) is being opposed by H. P. Bleckley, of the Abbey Electric Co. Full particulars will be found on another page of this issue.

5,638/09. **Ventilation of Ships.** J. KEITH (James Keith and Blackman Co., Ltd.) Opposition has been entered to the grant of this patent. The specification describes an apparatus comprising an electric motor driving a fan of the low-pressure, large volume type, and two adjustable flaps or valves for directing the air through, or to either side of, a heating or cooling device. The whole is enclosed in a casing, and connected by a pipe to a mushroom deck ventilator.

Applications for Amendment

12,739/02. **Manufacture of Incandescent Lamps.** A. SWAN (General Electric Co., U.S.A.). Swan's Patents, Ltd., desire to amend further this specification. (*See* ELECTRICAL ENGINEERING, April 29th, 1909, page 406.) The patent is for a lamp base or cap in which the metal shell is interlocked with a glass button uniting the contacts, when the glass is in a fused condition. The present amendment is to restrict the scope of the first two claims, and consists in adding details of the process described for automatically pouring in and moulding the glass.

28,546/07. **Track Brake.** E. FREUND seeks leave to amend this specification in order to restrict the scope of certain claims. The specification describes a track-brake mechanism in which the drag of the brake-shoes is utilised to operate toggles or rockers, which increase the pressure of the shoes on the track.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: ALLGEMEINE ELEKTRICITÄTS GES. [Transformer distributing system] 92/09; BANDFIELD [Attaching wires to insulators] 1,009/09; CLAREMONT AND STRATTON [Cable armouring] 6,809/09; OWEN [Wire insulating machine] 7,552/09.

Dynamos, Motors, and Transformers: AKT.-GES. BROWN, BOVERI, ET CIE. [Driving of ring-spinning frames] 26,225/08; VAN DAALEN [Dynamos and motors] 15,081/09.

Electrometallurgy and Electrochemistry: OZONAIR, LTD., and JOSEPH [Sterilisation of water] 27,226/08; COWPER-COLES [Welding aluminium] 27,260/08; BUNET and BADIN [Arc furnace for combining oxygen and nitrogen] 16,225/09; AKTIEBOLAGET ELEKTROMETALL [Furnaces] 17,342/09.

Heating and Cooking: BERRY [Heating apparatus] 1,414-5/09.

Incandescent Lamps: WEBER [Manufacture of filaments] 16,328/09.

Instruments and Meters: HORN [Voltmeters] 10,003/09.

Switchgear, Fuses, and Fittings: THOMAS and THOMAS [Relays] 20,772/08; FENNELL and PERRY [Lamp-holders] 26,752/08; JULIUS SAX & CO., and WHEAT [Cluster lamp fitting] 26,929/08; LAKE (*Cutler-Hammer Manufacturing Co.*) [Multiple switch-starters] 5,280/09; ENGEL [Fuses] 13,433/09.

Telephony and Telegraphy: ORLING [Electric impulse detector and recorder] 28,367/08; NICHOLSON [Telephone circuits] 604/09; BANDFIELD [Attaching wires to insulators] 1,009/09; SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*) [Telephone jacks] 17,994/09; BARDELONI [Aerial resonator for wireless plant] 24,187/09.

Traction: WAGNER [Signalling] 18,500/08; COLEMAN [Signalling] 18,670/08; TAYLOR [Brake-blocks and collector-shoes] 20,718/08; MITCHELL [Speed indicators] 26,429/08; RUSSELL and LORD [Splicing ear] 11,209/09; W. R. SYKES INTERLOCKING SIGNAL CO. and SYKES [Signalling] 16,446/09; COOPER [Brake block-holders] 17,335/09.

Miscellaneous: MAVOR, and MAVOR & COULSON, LTD. [Propulsion of ships] 26,569/08; WATTS [Illuminated signs] 1,765/09; MARTIN and JACKSON [Governing marine engines and turbines electrically] 2,900/09; BEST [Miners' safety lamps] 4,001/09; PRESTWICH [Miners' safety lamps] 5,158/09; WINDSOR [Burglar alarm] 21,161/09.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Storage Batteries: DE LAMINIÈRE and SOC. ANON. DES ACCUMULATEURS DE LAMINIÈRE [Plates] 27,976/09.

Telephony, &c.: SIEMENS & HALSKE AKT.-GES. [Telephone exchanges] 28,363/09; VON LEPEL [Wireless oscillatory discharge circuits] 28,452/09.

Traction: BALACHOWSKY and CAIRE [Axles of electric vehicles] 28,475/09.

Miscellaneous: SIEMENS & HALSKE AKT.-GES. [Signalling] 26,465/09 and 28,169/09; HARLÉ ET CIE. [Contact device] 28,164/09.

Amended Specification Published

The following amended Specification can now be obtained.

9,363/08. **Heat Accumulator.** C. NOTBOHN and O. ESTNER. This patent was amended as a result of the unsuccessful opposition to its grant. The specification was abstracted in ELECTRICAL ENGINEERING, July 1st, 1909, page 612.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Arc Lamps: IMPROVED ELECTRIC GLOW LAMP CO., and N. M. WATSHAM [Lowering winch] 19,406/04.

Distribution Systems, &c.: SIEMENS BROS. & CO. and E. M. NEALE [Expanding coupling for insulated cables] 17,974/05; E. C. LEA [Service cable connection] 18,016/05.

Dynamos, &c.: BRITISH THOMSON-HOUSTON CO. (*C. P. Steinmetz, U.S.A.*) [Converter armature connections] 16,127/06; V. MARTINETTO [A.-C. motors] 17,930/05; E. B. PHILLIPS and T. C. PARKIN [Commutator grinder] 18,208/05.

Electric Ignition: ELECTRIC IGNITION CO., and F. H. HALL [H.-T. ignition apparatus] 17,896-7/05.

Electrometallurgy and Electrochemistry: C. D. ABEL (*Siemens & Halske Akt.-Ges.*) [Smelting furnace] 19,366/05.

Incandescent Lamps: F. SODDY [Obtaining vacua] 17,933/05.

Instruments and Meters: A. MAY [A.-C. motor meter] 19,655/02.

Storage Batteries: CHLORIDE ELECTRICAL STORAGE CO., and P. M. BENEST [Tap for cell tank] 18,214/05.

Switchgear, &c.: W. H. ISHERWOOD [Sleeve coupling for wiring conduit] 19,365/04; T. S. JONES [Lamp-holder] 18,087/05.

Telephony and Telegraphy: G. MARCONI (*L. Solari, Italy*) [Iron-mercury-carbon coherer] 18,105/01; S. G. BROWN [Transmitter for duplexed cable lines] 19,251/03; H. CASEVITZ [Printing-telegraph] 19,553/03; C. G. ROSS [Relays] 17,955/05.

Traction: T. B. HOLLIDAY [Track brake] 19,601/03; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Multiple-unit control] 19,573/04; A. SUNDH [Multiple-unit control] 18,126/05; S. H. COWDY [Sanding device] 18,132/05.

Miscellaneous: CROMPTON & CO., R. E. CROMPTON, A. J. HODGSON, and J. W. EWART [Searchlights] 18,169/01; NATIONAL CASH REGISTER CO. [Cash Registers] 19,161/04; H. KOWSKY [Electro-hydraulic power transmitting device] 17,949/05; R. P. WILSON and A. G. MARSHALL [Ventilating fans] 18,005/05; F. S. POVAH and S. G. LIVEIT [Electrolytic rectifier] 18,015/05.

ELECTRICITY SUPPLY IN TOKYO

THE generating stations and the transmission lines of the Tokyo Electric Light Co., which was established 1893 with a capital of 200,000 yen (about £20,000), are described in a recent issue of the *Electrical World* (New York). Since 1893, by buying over or amalgamating with other companies, the company steadily increased in importance, until it became, in June, 1906, a concern with a capital of £715,000, having a generating plant of some 11,000 kw. capacity and also a monopoly of the electric lighting business for the entire city of Tokyo and suburbs. Previous to this, in 1904, the company decided to engage in the development of the water-power of adjacent districts, and in pursuance of investigations carried out at that time and in execution of rights already secured in 1899 in making use of the River Katsura, in Yamanashi Prefecture, various preparatory measures, such as actual surveying, buying up land, &c., were completed in 1905. The work of construction for the new power plant at Komahashi was started in January, 1906, and was finished in February, 1908. As a result a total amount of power corresponding to 25,500 B.H.P. at the turbine shafts was obtained, and the company was enabled to discontinue entirely the use of its former steam plants. For 11,372 ft. the water runs in open canals. The gradient of the water course is 1 in 1,200 in the tunnels and 1 in 2,400 in the open canals, the difference of water levels between the intake and the penstock chamber being 13 ft. 9 in.

The company has only one intake on the river. The quantity of water utilised is 750 cubic ft. per second, producing 22,500 H.P. at the turbine shafts at an effective head of 345 ft. The length of water course between the intake and the penstock chamber at Komahashi is 22,229 ft. The water course contains nine tunnels, the longest of which is 3,114 ft. The aggregate length of all the tunnels is 10,857 ft. Recently, the company has amalgamated with the Tokyo Electric Power Co., thus further securing water rights. The additional work will require three years for completion, and the result is expected to yield an additional 50,000 B.H.P.

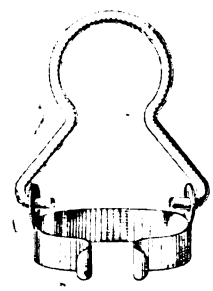
The sets installed in the Komahashi generating station consist of double Francis turbines direct-coupled to three-phase generators. The turbines are of the double-reaction type, each capable of giving 4,500 B.H.P. at 500 r.p.m. The generators are of the revolving-field type, each having a rating of 3,900 kva. at 6,600 volts. The generating station contains six of these generating sets, and two sets of exciters direct-coupled to Pelton waterwheels, rated at 265 B.H.P. at 600 r.p.m. Each exciter-generator has a rating of 180 kw. In addition, there are nine 2,000-kw., single-phase step-up transformers, which raise the pressure to 57,000 volts to Waseda, forty-seven miles distant. At the Waseda receiving station nine 1,800-kw. step-down transformers are installed. Here the pressure is reduced to 11,000 volts for distribution to the Tokyo city sub-stations by underground cables. Between the Komahashi generating station and the Waseda receiving station the energy is transmitted over a double pole line. Some steel towers are used, but wooden poles are mostly employed. In all there are 4,100 poles, the distance being forty-seven miles. Each of the six conductors is a bare copper cable 105 mils in diameter, consisting of eighteen strands.

On account of the rapidly increasing demand for electric lighting the company has found even its present large water-power plant insufficient to meet requirements, and it will thus make immediate use of the new station. In the meantime, as the load gradually increases, recourse will be made to the old steam plant, which is always kept in order as a reserve.

The River Katsura, from which the company obtains its power supply, has its source in Lake Yamanaka, which in turn is fed by subterranean streams that drain through the sides of Mount Fuji and the surrounding ranges. The altitude and humidity being favourable, there is no danger at any time of the lake drying up. Furthermore, the land immediately surrounding the lake is of such a character that all flood water can be absorbed, and there is, therefore, no danger of the lake ever overflowing even after exceptionally heavy rainfalls. The River Katsura may, in consequence, be said to possess two qualifications necessary for electrical purposes, namely, unfailing supply of water and non-fluctuation in flow.

The total cost of construction of the 22,500-H.P. installation now in service was about £600,000, or about £26·5 per horse-power. The capital stock of the company at the present time is about £2,400,000, of which about £1,800,000 has been paid up.

Telephone over the Alps.—The *Pall Mall Gazette* Geneva correspondent states that direct telephonic communication between Germany and Italy over the Swiss Alps will, in all probability, be opened next year. This will be the first trans-Alpine telephone line covering a great distance. The existing lines between Milan and Chiasso, and between Frankfort and Basle, will be employed, but a new station will be erected near the summit of the St. Gothard Pass to fill the gap across Switzerland, and to afford direct communication between the two frontier towns.



COPPER IN 1909

WE have been favoured with an advance proof of Messrs. Bolling & Lowe's Trade Review for 1909. Under the heading, "Copper," it is stated that the past twelve months have been noteworthy by reason of the enormous speculative dealing for the rise, which has resulted in a remarkably steady market, notwithstanding the constant deterioration apparent in the statistical position. High water-mark in prices was touched in January at £64 3s. 9d., and low water-mark was reached in March at £54 10s. The prices during the greater part of the year moved between £58 and £62, and it was round about this range that the bulk of the huge speculative commitments was opened up. These operations were based upon a belief in, or a fore-knowledge of, an impending consolidation of leading interests in North America headed by the Amalgamated Copper Company, and those at the back of the operations have kept continuously to their holdings through good report and evil. The negotiations, which have been very protracted, resulted in a basis of agreement being reached, but the plans formulated for carrying it into effect have been disturbed by the now historic declaration that the Standard Oil Company is an illegal Corporation, and pending the discovery of some means of evading the law, as at present interpreted, the proposed copper merger, following the lines of the oil trust, has been postponed. There is no doubt that in some form or other the consolidation will take effect, in which case the interests concerned will control probably 50 per cent. of the North American output of copper, the chief parties to it being the Amalgamated, Guggenheim and Cole-Ryan Groups. Already, as a result of the negotiations and of the better feeling existing between all United States copper producers, steps are being taken to control production by 10 per cent., and this, if put into effect, should wipe out the overplus of output seen this year.

Given an organisation strong enough to regulate North American production, the adjustment of prices to a level satisfactory to the dominating interests becomes a comparatively simple matter, although it is one which under the circumstances of to-day is calculated to be of most value to outsiders. It is hoped, however, that when once the projected American consolidation comes into being, it will be merely a matter of time and diplomacy for a working arrangement to be made including all the more important producers in the world. This is the hoped for goal, but its attainment may be a long way off yet, though meantime the copper market is kept well in hand. [We refer our readers to our weekly "Price of Copper."]

A LAMP-HOLDER SUSPENSION CLIP

THE accompanying illustration represents a lamp-holder suspension clip recently designed by Mr. C. W. Denny, which is being placed upon the market by the Clarence Engineering Co., Ltd. (3 Cherry Tree Court, Aldersgate Street). This clip is intended for attachment to any ordinary lamp-holder for the purpose of suspending the lamp from a wall, bracket, or shelf, and, in fact, any place where a vertical cord hang is not permissible. This device is extremely advantageous in shop-window lighting, bazaars, and other places where lamp-holders have to be suspended in awkward or difficult positions. The use of this clip prevents any nails, hooks, or other metallic appliances coming in contact with the flexible connections, and thus prevents them becoming frayed and the insulation weakened when used as a means of support for the lamp-holder. A further advantage is that the weight of the lamp-holder or pendant is removed from the flexible connections. It is a very common practice at Christmas and other times to attach festoons or other fixings from the lamp-nolder, which often interfere with the flexible leads, and also put a considerable strain on the cord grip attachments.

THE DENNY LAMP-HOLDER SUSPENSION CLIP.

A Cable Ship in Collision.—The vessel which collided with the P. & O. liner *Nile* in the Thames on Christmas Eve was a cable ship named the *Telconia*, which had only recently been completed for the Telegraph Construction & Maintenance Co. by Messrs. Swan, Hunter & Wigham Richardson. The ship is 223 ft. in length over-all, and has a deadweight capacity of 1,000 tons. The cable equipment was designed and manufactured by the Telegraph Construction & Maintenance Co. themselves, and embodied a number of improvements due to Mr. F. R. Lucas, Managing Director. Contrary to usual practice, the crew are quartered aft, to leave the whole of the space forward of the bridge for cable work. The two cable-tanks have a coiling space of about 8,000 cubic feet. It is reported that the *Telconia* is seriously damaged on the starboard quarter.

LOCAL NOTES

ARGENTINE: *Tramways.*—The *Review of the River Plate* states that Mr. E. C. Steer has deposited 10,000 dollars in relation to his proposal to build an electric railway from Montevideo to Colonia. It is expected that the first section of the La Plata Electric Tramways will be opened on January 1st. There are five sections in all, and it is hoped to open these at intervals of three months.

AUSTRALIA: *Overhead Wires.*—According to the *Australian Mining Standard*, a deputation recently waited upon the Queensland Minister of Works with regard to the provisions in the Electric Lighting Act of 1896, concerning overhead wires. The deputation in question was appointed by the Electrical Association of Queensland, and expressed the view that so long as the present provisions were allowed to remain on the Statute Book, electrical progress would be considerably hampered. It was alleged that in consequence of the present law only four towns in Queensland had adopted electric light. Under paragraph 2 of Clause 24 of the Act, any local authority could pull down overhead wires, despite the fact that they had been erected in accordance with the regulations. This was a deterrent to electrical supply companies. The result was that many small towns were without electricity, where otherwise works would have been erected. The Minister of Works, in reply, said that the first consideration of the Government was the protection of the public. The Government did not wish to hamper the electrical industry, and he would remit the question for expert opinion, after which it would be submitted to the Cabinet. The Government, however, was so busy that he could not hold out any hopes of the question being dealt with in the present session of Parliament.

BERLIN: *Purchase of Tramway Undertaking.*—The Corporation are once more considering the desirability of purchasing the undertaking of the Berlin Tramways Company. The purchase price asked by the company is said to be about 200,000,000 marks.

BEXLEY: *Tramway Undertaking.*—The accounts of the Tramways Department for the year to March 31st, 1909, show a deficit of £1,303.

Electric Lighting Accounts.—The Electric Lighting accounts for the year to March 31st, 1909, show a deficit of £503.

BISHOP STORTFORD: *Electric Lighting.*—With reference to the scheme of electric lighting proposed by Messrs. May & Hawes, and referred to in our last issue, a ratepayers' meeting has considered the matter and passed a resolution that the question should stand over until the ratepayers are more cognisant of the proposals made.

CHIPPENHAM: *Electric Lighting Order Revoked.*—The Board of Trade have revoked the Electric Lighting Provisional Order granted to the Corporation in 1904.

CHRISTCHURCH (N.Z.): *Electricity Accounts:* The report of the City Electrical Engineer to March 31st shows a total revenue of £1,304, and a working expenditure of £7,288. After meeting interest, sinking fund charges, and depreciation, there is a net profit of £1,327. The total number of units sold was 776,126.

FIFE: *Tramway Extension.*—The section of the Dunfermline & District Tramways from Cowdenbeath to Lochgelly was opened last week, after inspection by Colonel Von Donop, on behalf of the Board of Trade.

GILLINGHAM: *Electricity Undertaking.*—Mr. J. F. C. Snell has now presented his report upon the general position of the electricity undertaking of the Council. He states that the primary causes of the Council's present troubles are:- (1) Heavy and unnecessary capital expenditure; (2) the system adopted, which was not the most economical for the district. He cannot now, however, recommend any serious change of system owing to the capital expenditure which would be involved. So far as the present management of the undertaking is concerned, Mr. Snell considers the coal consumption and wages are too high. The remaining costs are quite satisfactory. He does not intend his criticism as to coal costs to be any reflection upon the Borough Electrical Engineer, as the weight of coal per unit sold will always be high, owing to the inefficiency of the system in use. After having considered the question of taking supply in bulk from the Kent Electric Power Co., and the installation of a Diesel engine and alternator by the Council, Mr. Snell decides in favour of the latter. Mr. Snell considers that it will be several years before the undertaking can possibly be expected to pay its way, and the only immediate result which can be expected is a diminution of the losses. He believes that the installation of the Diesel day load plant will result in an immediate saving of over £1,000 per annum. Mr. Snell's suggestions, including the Diesel engine and alternator, involve an outlay of £3,300, and, after a long discussion, the Council has decided to adopt the suggestions, and put the work in hand at once. The system in use at Gillingham is high-tension, three-phase, with transformers in substations, and four-wire distribution.

HANLEY: *Vibration from Electrical Machinery.*—At the Hanley County Court last week a case was heard in which the owner of a dwelling house next to the premises of the Stoke-on-Trent Pure Ice & Cold Storage Co., Ltd., sought to restrain this company from using certain electrical machinery which he alleged caused vibration and noise. It was complained that the machinery was kept running for excessive periods, sometimes as long as 22½ hours continuously, and the result was that "trembling" was felt in every room of the house. It appears that the company have a 40 h.p. electrical motor at work. After hearing evidence, judgment was reserved until January 12th.

HASLINGDEN: *Electricity Supply.*—The Borough Engineer has been instructed to prepare a report upon the cost of laying electric cables within the compulsory area scheduled in the Council's electric lighting order.

LONDON: *Paddington: Tramways.*—The Borough Council have decided to oppose the tramways proposed by the L.C.C. along Wood Lane to Harrow Road via Westbourne Park Road.

Woolwich: Electrical Showrooms.—The Electricity Committee recommend an application to the L.C.C. for sanction to borrow £3,000 to purchase premises at 44 Powis Street, Woolwich, for the purpose of electrical showrooms.

PORT GLASGOW: *Electricity Supply.*—At the monthly meeting of the Town Council last week, the question of taking a supply of electricity from the Greenock Corporation was once more discussed. The Council have appointed a sub-committee to deal with this matter, but an effort was made to induce the Corporation to consider first of all the desirability of erecting their own electricity work. The proposal was negatived, however, and the sub-committee will proceed with its work of investigating the proposals made on behalf of Greenock.

STOKE-ON-TRENT: *Tramway Fares.*—The Potteries Electric Traction Co. is to be asked by the Council to retain the existing system of fares upon certain sections of the tramways in Stoke. Apart from this, the Council has expressed approval of the new "fair fares" system, but are of the opinion that the minimum fare should be ½d. instead of 1d.

SURREY: *Proposed Electric Railway.*—A meeting of Merton property owners has passed a resolution approving of the proposed electric railway between Wimbledon and Sutton.

WALTHAMSTOW: *Power Rates.*—From January 1st the charge for power to consumers of 30,000 units and over per annum is to be reduced to a penny per unit.

YARMOUTH: *The Pier Fire.*—The Electricity Department of the Corporation contradict the statement that the cause of the outbreak of fire on Yarmouth Pier last week was due to the electrical installation. As a matter of fact, neither the pier nor the pavilion was connected to any electrical mains.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRALIA.—A scheme has been presented to the Boulder (W.A.) Council, involving a loan of £8,000 for extensions to the electricity works.

The Melbourne City Council require an electrically-driven pump. Particulars from Messrs. McIlwraith, McEacharn & Co., Ltd., Billiter Square Buildings, London, E.C., and tenders by February 2nd.

BELFAST. The Tramways and Electricity Committee invite tenders for a 1,500-kw. continuous-current turbo-dynamo with condensing plant. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by January 10th.

BIXHILL.—A Local Government Board inquiry was held last week regarding an application by the Council for sanction to borrow £1,500 for feeders, and £300 for the replacement of gas lamps by electric lamps.

BRIGHTON. The Council invite tenders for:—(1) 3,000-kw. three-phase alternator with condensing plant and direct-coupled exciter; (2) 1,500 h.p. 8,000-volt three-phase induction motor; (3) 300-kw. induction motor-driven balancer set; (4) high-tension switchgear of the self-contained iron-clad type for the above. Particulars from the Town Clerk, to whom tenders by January 10th.

EASTBOURNE. Tenders are invited for a steam-driven surface condensing plant. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by January 17th.

ECCLES.—The Corporation require a 150-kw. steam engine and D.C. dynamo. Particulars from the Borough Electrical Engineer, Cawdor Street, Patricroft, and tenders to the Town Clerk by January 15th.

ERITH. The Council invite tenders for a high-tension three-phase alternating-current switchboard. Particulars from the

Digitized by Google

Engineer, Electric Lighting and Tramway Offices, Walnut Tree Road, Erith, and tenders to the Town Clerk by January 10th.

LONDON: *Fulham.*—Two extra transformers with connections are to be added to the sub-station of the Metropolitan Asylums Board at the Western Hospital, at a cost of £92 10s.

MANSFIELD.—A sub-committee has been appointed to consider the question of extending the electricity works.

Miscellaneous

AUSTRALIA.—Tenders are invited by February 2nd for the supply, delivery, and erection at the Telephone Exchange, General Post Office, Sydney, of two junction line sections of common battery switchboard, in accordance with Schedule N.S.W., E.E., 63/09. Preference will be given to tenders complying most closely with the department's requirements for prompt delivery. Preliminary deposits may be paid at the Commonwealth Offices, in London, 72 Victoria Street, S.W.

Tenders are invited for the supply and erection of two wireless telegraph installations, one at Sydney and one at Fremantle. Tenders must include alternative quotations for stations with a range of 500 miles, and 1,000 miles. Tenders to the Secretary, Postmaster-General's Department, Melbourne, accompanied by a deposit of £100, by February 22nd. Particulars may be obtained from the Commonwealth Office, 72 Victoria Street, London, S.W.

BRAZIL.—Mr. R. J. Reidy has been granted a concession for laying a submarine cable between Belém (Para) and Nictheroy (Rio Janeiro). The cable will pass by way of the Island of Fernando de Noronha and the town of Maceio in the State of Alagoas. The concession also includes the laying of a cable between Nictheroy and Chuy (State of Rio Grande do Sul), passing by way of Santos (State of S. Paulo). The concession for both these cables is for a term of 25 years.

ITALY.—The Italian Ministry of Marine invite tenders for the supply of electric lamps and lamp-holders by January 11th, 1910. The specifications and conditions may be obtained from the Italian Admiralty Offices at Spezia, Naples, Venice, and Taranto.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

LONDON.—Tenders are invited for the wiring and fitting of the new premises of the Institution of Electrical Engineers on the Victoria Embankment. Particulars and forms of tender from the consulting engineers, Messrs. Handcock & Dykes, 1 Victoria Street, Westminster, London, and tenders to the Secretary, 92 Victoria Street, London, by January 10th.

W.—Block of shops, Uxbridge Road, Shepherds Bush, W. (£6,600). Architect, F. H. Witts, 39 Agate Road, Hammersmith. Builders, Kingerlee and Sons, Queen Street, Oxford.

S.W.—Building, Wilfred Street, Buckingham Gate, S.W. Builders, Barlow and Roberts, 15 Redcross Street, Southwark, S.E.

S.E.—Building, Rockingham Street, Southwark S.E., for John Newton and Co., hair felt manufacturers, Verney Road, Rotherhithe, New Road, S.E.

PROVINCES.

ABERYSTWYTH.—Isolation Hospital. Clerk to the Town Council.

BELFAST.—The Committee of Management of the Belfast & District Asylum invite tenders for the wiring and fitting of the new asylum buildings on the Purdysburn Estate. Particulars from Messrs. Watt, Tulloch, & Fitzsimons, 77A Victoria Street, Belfast, and tenders by January 10th.

COLNE.—Additions to mill for Calf Hall Shed Co. (£3,000). Architect, W. H. Atkinson, Colne.

DURHAM.—Additions to Close House Elementary School (£3,000). Architect, F. E. Coates, Shire Hall, Durham.

DUNDEE.—Extensions to Clepington Public School (£2,150). School Board architect, J. H. Langlands, Dundee.

EXETER.—Headquarters for Artillery Brigades (£5,000). Architects, Dymond and Parsons, Southernhay, Exeter.

KEIGHLEY.—Business premises and works (£2,000). Architect, D. Weatherhead, Keighley.

MIDDLESBROUGH.—Library (£11,500). Builder, H. McNaughton, Snowdon's Road, Middlesbrough.

NOTTINGHAM.—Additions to Boys' High School (£2,000). Architects, Evans and Sons, Wheelergate, Nottingham.

OLDHAM.—Church Institute (£2,500). Architect, C. Taylor, 10 Clegg Street, Oldham.

PLYMOUTH.—Territorial headquarters, Millbay. Architect, F. A. Clark, 83 Old Town Street, Plymouth.

READING.—Offices for Berkshire County Council (£16,400). Architects, Warwick and Hall, 13 South Square, Gray's Inn, W.C. Builder, E. C. Hughes, Wokingham.

WOKING.—Extensions to Monument Hill Schools (£1,314). Builders, G. Kemp and Co., Aldershot.

TENDERS RECEIVED AND ACCEPTED

LONDON: *Southwark.*—The Council have placed an order with Sanders, Rehders & Co., Ltd., for a "Sarco" combustion recorder for the electric light station at £34 10s.

OBAN.—The tender of Messrs. Callender's Cable & Construction Co., Ltd., has been accepted for new cables at £382, less £20 10s. allowance for old cable to be drawn out.

KINGSTON-ON-THAMES.—The Corporation have placed an order with Mr. Haydn Harrison for thirty Croydon type fittings for street lighting at £1 10s. each.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £62 5s. to £62 15s. per ton (last week, £61 15s. to £62 5s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the Eldon Electric Co., Ltd., will be held at the offices of Messrs. Dickenson, Miller & Turnbull, 46 Grainger Street West, Newcastle-upon-Tyne, on January 31st, at 11 a.m., to hear the liquidator's account of the winding up.

CANADIAN AGENCIES WANTED.—A firm of engineers near London manufacturing a trolley standard earthing device, two-blade rail cleaners, tangential suspension for overhead lines, suspension gear for E.H.T. transmission lines, block signalling apparatus, switchgear, &c., for street railways, is desirous of opening a Canadian agency.

A correspondent, who is shortly proceeding to Toronto, wishes to obtain some sole agencies of United Kingdom manufacturers of machinery used in collieries, iron and steel works, mines, &c.

Particulars may be obtained from the office of the High Commissioner for Canada, 17 Victoria Street, London.

AGENCY.—Messrs. Watson & Whyte, of 19 Waterloo Street, Glasgow, have taken over the agency for Messrs. Feld Bros.' (25 Budge Row, London) portable electric circular saws, for Glasgow and district. We illustrated and described this saw in our issue for November 11th, p. 964.

MISCELLANEOUS CITY NOTES

ANGLO-ARGENTINE TRAMWAYS CO.—Dividends of 2s. 6d. per share have been declared upon the first and second preference shares for the December half-year.

BERLIN TELEPHONE CO.—A dividend of 11 per cent. is announced for the financial year just closed.

MEXICAN LIGHT & POWER CO.—The directors propose to increase the preference stock by $3,600,000, and the ordinary stock by $5,400,000, bringing the total capitalisation up to $6,000,000 preference stock, and $19,000,000 ordinary stock. The money is mainly required in connection with the new water-power plant.

LONDON UNITED TRAMWAYS.—A circular issued by the directors states that the preference dividend due on January 1st is not to be paid for the present.

DIRECT WEST INDIA CABLE CO.—An interim dividend of 6 per cent. per annum free of tax has been declared on the ordinary shares for the December half-year.

RAWORTH'S TRACTION PATENTS.—The capital of this Company by order of the High Courts has now been reduced from £30,000 to £20,635.

CALCUTTA ELECTRIC SUPPLY CORPORATION.—*The Financial Times* states that negotiations for the placing privately of £100,000 cumulative five per cent. £5 preference shares of this company are still proceeding, and will, it is believed, prove successful. The technical legal difficulty which put a stop to the negotiations temporarily is being surmounted by mutual concessions between the company and its friends.

Telegraph Traffic.—On the 20th inst., the cable between Obok and Djibouti and between Tourane and Amoy broke down, and telegrams are sent daily from Obok by boat.—The Hanekin route was also down between Alep and Bagdad and between Mossoul and Bagdad on the 20th for a short while.—The Bagdad-Bassorah line was restored to working order on the 24th, and failed again on the 26th inst.

The Commercial Cable Co., founded in December, 1884, celebrated its silver jubilee on Tuesday evening at the Great Eastern Hotel, London, when Mr. C. H. Mackay, president of the company, entertained the staff at an informal dinner.

Theft of Wireless Apparatus.—The Admiralty draughtsman, Richard Sydney Knowlden, who is charged with stealing a wireless telegraph receiver, value £5, from the Vernon Torpedo School, was before the Portsmouth magistrates again on Tuesday. The accused is now charged with contravening the Official Secrets Act by taking drawings of wireless telegraph apparatus from H.M.S. *Vernon*. It is stated that in his house two wireless receivers and other instruments of a confidential character were found, and also some 80 drawings of wireless telegraph apparatus. One of the drawings related to a new form of detector, in which mineral substances were used. The accused was committed for trial at the Hants Assizes, bail being allowed in two sureties of £500 each.

Digitized by Google

COMPANIES' MEETINGS AND REPORTS

ELECTRICAL SECURITIES TRUST.—The report for the year to November 14th, after providing for debenture interest, shows a loss of £5,442, increasing the debit balance to £10,486.

MANX ELECTRIC RAILWAY CO.—The gross receipts for the past year were £32,745, and the expenditure £16,508. After meeting debenture and preference interest, the sum of £1,126 is carried forward. The result is not so good as in the previous year, and the directors attribute this mainly to bad weather.

COMPANIES STRUCK OFF REGISTER.—The names of the following companies will be struck off the Register of Joint Stock Companies at the expiration of three months, unless cause is shown to the contrary:—Electrical Bleaching Co.; Electrical Regulating & Lighting Syndicate; Electrical Supplies, Rubber & Evonite Co.; Electric Lamp Regenerating Co.; Electric Railways Co.; and Meyra Electric Co.

MANX ELECTRIC RAILWAY CO.—The receipts during the past year amounted to £32,745, against £33,734 in the previous year, whilst working expenses were £16,508, compared with £16,733. At the meeting on Tuesday the report and accounts were adopted. The directors recommended payment of the debenture interest and preference dividend, carrying forward £1,126. The Chairman regretted that nothing had been done towards superseding the present antiquated horse tramways in Douglas by electric cars, and pointed out that Douglas could not afford to fall behind Blackpool and other seaside places in Lancashire.

DURHAM COLLIERIES ELECTRIC POWER CO.—The report shows a gross profit of £5,265, but after charging various expenses and writing off a bad debt of £7,362, there is a debit of £8,786. To this has to be added the prior lien debenture interest, and the first mortgage debenture interest, which brings the total loss for the period of eighteen months ended September 30th, 1909, to £21,713.

MELBOURNE ELECTRIC SUPPLY CO.—At the annual meeting last week the report and accounts given in our last issue were adopted. Mr. J. B. Braithwaite, the Chairman of the company, stated that the capital had now been reorganised, and they had been enabled to wipe out the heavy loans which had been hanging around the neck of the company during the last two years, when the only means of obtaining further capital was by borrowing. The cost of the reorganisation was £22,789, and they had already transferred £11,750 from the reserve account, thus reducing the liability under this head to £11,039. The directors, further, recommended the transfer of a further sum of £2,039 to this account out of the revenue for the past year, leaving only £9,000 to be wiped off, and this sum they propose to extinguish in three equal amounts of £3,000 out of revenue during the next three years. The business of the company was making steady and satisfactory progress, both in volume and in profit, and he thought they could be well satisfied with the position and prospects of their undertakings, both at Melbourne and at Geelong. The Chairman, in conclusion, announced that the directors hoped to put forward a scheme early in the New Year with a view to dealing with the arrears of dividends upon the old preference shares, which were now converted into preference stock.

SUNDERLAND DISTRICT ELECTRIC TRAMWAYS CO.—The report for the year to October 31st states that, after providing for interest on the prior lien bonds, first and second mortgage debentures, and loans (£9,730), there is a loss on the year of £780. This brings the loss to date to £14,604. During the past year the traffic receipts decreased by £1,319, but a saving was effected in the working expenses of £2,108.

Wireless Telegraph Notes.—The Lepel Wireless Syndicate, Ltd., has experimental stations at Twickenham and Slough. At the latter station is an interesting piece of apparatus comprising a series of oscillating circuits of different frequencies which can be connected to the aerial in any desired sequence by means of a keyboard. According to the *Elektrotechnische Zeitschrift*, the British national anthem was transmitted by means of this apparatus and received successfully on the telephonic receivers at Scheveningen and at the Eiffel Tower.

According to the *Electrical World* (New York) an American patent has been granted to R. A. Fessenden for a method of locating the position of ships by means of wireless telegraphy. According to the arrangement proposed, signals are sent out at regular intervals from two or more fixed stations, each vessel locating its own position by comparing the strengths of the signals received. Each land station sends out a distinctive signal so that it may be recognised immediately by any vessel. Moreover, the strength of the signal from each land station is varied so as to form a succession of signals of gradually varying intensity so that each signal shall produce the same intensity at a point 20 miles farther from the station than the signal immediately preceding it. Thus the operator on each vessel first identifies the station from which each signal is being sent, estimates the relative distances from the vessel to each land station, and thereby determines the position of the vessel.

There are now four wireless telegraph stations in Morocco, viz., at Tangier, Rabat, Casablanca, and Mogador.

Electrification of Melbourne Suburban Railways.—*The Australian Mining Standard* gives the judgment in the action taken by a Mr. F. E. Bradford against the Victorian Government for breach of contract in connection with an engagement to report upon the electrification of the Melbourne suburban railways in 1904. The plaintiff claimed £3,500 damages. He alleges that an agreement was come to between the late Sir Thomas Bent, Premier of Victoria, and himself under which he was to receive £2,000 for reporting upon the electrification of the Melbourne railways and the South Australian railways. It will be remembered that Mr. C. H. Merz subsequently went from England to Australia, and reported with regard to the Melbourne railways. When the action was first tried, the jury could only give a majority verdict, but this the Crown refused to accept. In the second action, in which judgment is now given, the jury found for the plaintiff for £1,328, with costs.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of 9d. per line (column width).

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of 1/- for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to THE KILOWATT PUBLISHING CO., LTD., 203-6, Temple Chambers, London, E.C.

BATTERSEA POLYTECHNIC, S.W.

Principal: S. G. RAWSON, D.Sc.

EVENING CLASSES RE-OPEN JANUARY 10th.

ELECTRICAL ENGINEERING.

Head of Department: A. W. ASHTON, M.Sc.

The following special evening courses are being held:

Alternating Currents.
Electric Traction.
Design of Alternating Current Machinery.
High Tension Transmission.

For Prospectus and full particulars apply to the Secretary.

CRYSTAL PALACE PRACTICAL SCHOOL OF ENGINEERING.

Principal: J. W. WILSON, M.I.C.E., M.I.M.E.

The first term of the 38th year will open on Wednesday, January 5th. New Students should attend at the School on the previous day between 10 a.m. and 1 p.m. for examination. Prospectus forwarded on application to the Registrar, School of Engineering, Crystal Palace, S.E.

NORTHAMPTON POLYTECHNIC INSTITUTE, ST. JOHN STREET, LONDON. E.C.

DEPARTMENT OF ELECTRICAL ENGINEERING AND APPLIED PHYSICS.

THE GOVERNING BODY invite applications for the post of Associate Head of the above Department. The salary attached to the post is £400 per annum. Further particulars and forms of application, which should be returned to the undersigned not later than 10 a.m. on Monday, 10th January, 1910, may be obtained from

R. MULLINEUX WALMSLEY, D.Sc.,
Principal.

ELECTRIC CABLE CASING. Special clean white 1½ in. at 22/6, 2 in. at 35/6 1000 ft. Refuse foreign. Support BRITISH industry. We compete, own make. All sizes in stock, also cable troughs for underground, woodwork all description. Send trade card. C. JENNINGS & Co., 955, Pennywell Road, Bristol.

GAS RETORT CARBON for Sale. Pitch, Insulating Material, Creosote. We supply the Trade.—V. DASNIERE & 10, St. Mary Axe, London, E.C.
